

# **One-Fish, Two-Fish, Red-Fish, Blue-Fish:**

Results from Recent Snorkel Surveys of  
Rainbow Trout in the Lee's Ferry Reach of  
the Colorado River

Josh Korman, Mike Yard, Dave Speas

Supported by AGF - GCMRC

# Objectives of Snorkel Surveys

- Boat electrofishing is used to estimate Catch Per Effort (CPE) of shoreline areas. It is the primary method of indexing rainbow trout abundance in Lee's Ferry
- Use snorkel surveys to evaluate assumptions inherent in boat electrofishing.

$$CPE = q * N$$
$$q = q_{\text{shore}} * q_{\text{off-on}}$$

offshore

shoreline

•  $q$  is constant

•  $q$  is independent of  $N$

- Evaluate potential as a long-term monitoring tool to supplement electrofishing program

# Components of Snorkel Survey Program

- Daytime shoreline surveys at 36 sites (9 fixed, 27 random)
  - 3 replicated counts as an index of density/site
  - Compare with nighttime boat EF densities
- Cross-sectional transects at each shoreline site
  - 6 replicated estimates of apparent density in shoreline and offshore areas
- Diel survey at up to 3 sites
  - Changes in apparent density in offshore and shoreline areas due to movement and catchability responses to discharge and light

# Summary of Sampling Effort

	Snorkel			EF vs.

# Diel Study Sites

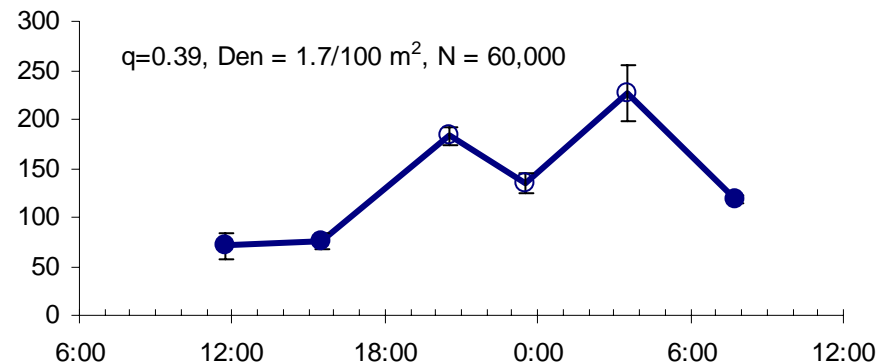

# Alternate Models for Interpreting Diel Count Data

- Model 1: Equal  $q$  across lanes and time
  - Differences in counts among lanes over time represent real differences in density (note:  $N_{1-6,t} = N_{1-6,t+1}$ )
- Model 2: Equal  $q$  across lanes, but not over time
  - Differences in counts among lanes within a time period represent real differences in density
$$C_{x,t}/C_{x+1,t} \neq C_{x,t+1}/C_{x+1,t+1} \quad \text{caused by movement}$$
- Model 3: Unequal  $q$  across lanes and time, but relative differences in  $q$  among lanes are constant over time
  - Counts by lane dependent on both density and catchability
$$C_{x,t}/C_{x+1,t} \neq C_{x,t+1}/C_{x+1,t+1} \quad \text{caused by movement}$$
- Model 4: Unequal  $q$  across lanes and time, relative differences in  $q$  among lanes are not constant over time
$$C_{x,t}/C_{x+1,t} \neq C_{x,t+1}/C_{x+1,t+1} \quad \text{caused by movement or changing } q$$

# Mechanism to Explain Reduced Offshore-Shoreline Ratio in Oct. Sample

# Snorkel – Electrofishing Shoreline Density Comparison

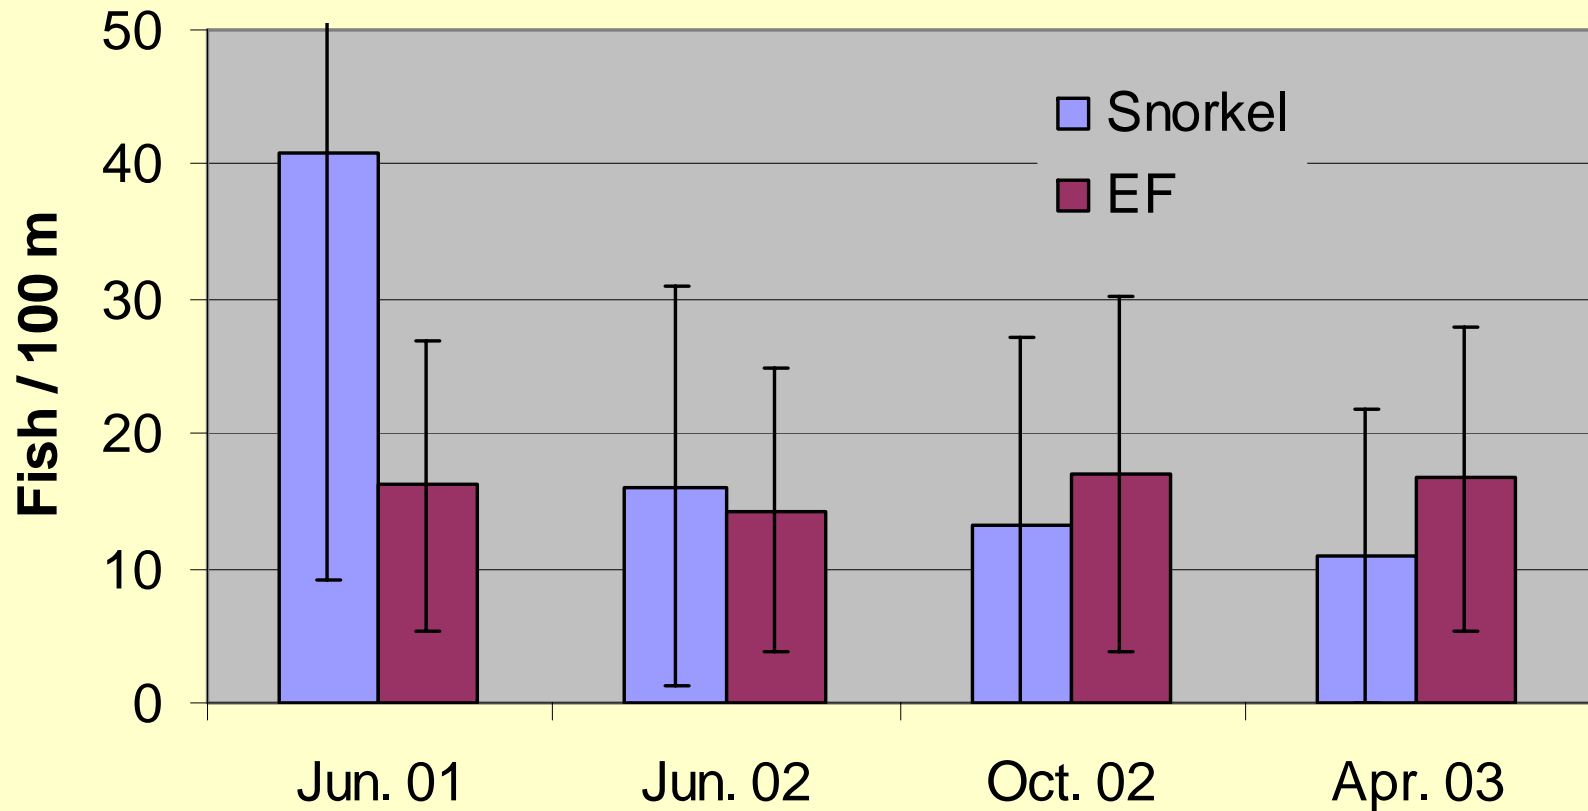

# Snorkel – Electrofishing Shoreline Density Comparison

# Comparison of Snorkel vs. EF Densities

# Conclusions

- Potential Causes for EF vs. Snorkel Trend discrepancy
  - There is no discrepancy if sampling variance is considered
  - No population trend from '01-'03, EF is OK and snorkel has some unknown bias
  - -'ve population trend from '01-'03, Snorkel is OK and EF is hyperstable.
- Magnitude in trend from diel sites matches trend seen in shoreline sites (1.5↓ Jun. '02-Apr. '03 at 8 Mile Bar)
- Possible mechanisms for hyperstability:
  - Dipper saturation (can count fish faster than they can be dipped)
  - EF sampling highest density of fish (nighttime, high flow, shoreline) where density changes over time would likely be smallest
- Biological evidence of a recent population decline
  - 2000 LSSF and low flows since then compared to late '90s = less food base
  - PSD and condition factor were below the declining trend after 2001+
  - Many dead/sick fish observed during '01 snorkel survey
