

Seasonal Outlook for the next three months

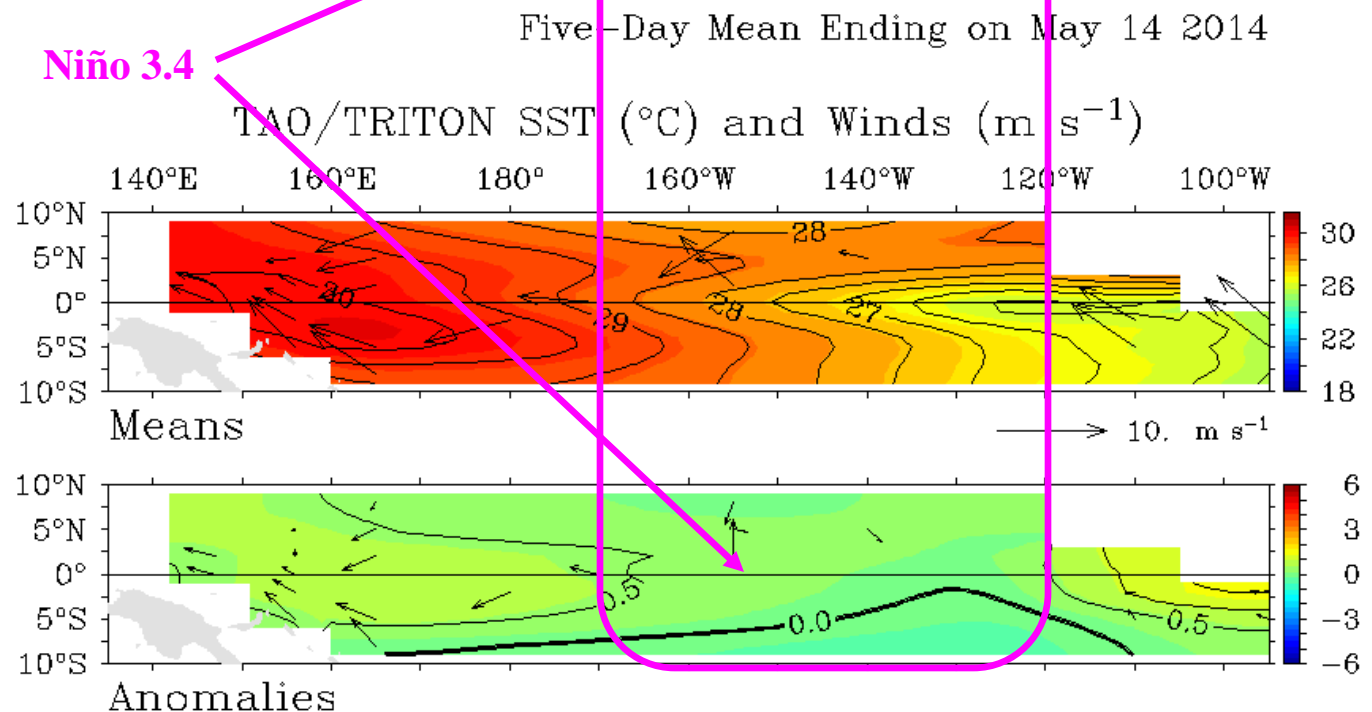

Klaus Wolter

University of Colorado, CIRES & NOAA-ESRL PSD 1, Climate Analysis Branch

klaus.wolter@noaa.gov

- **What has happened to ENSO(+), what will happen next, and what does that mean for us ?**
- **Expectations for the next two weeks**
- **CPC forecasts for July through September 2014**
- **Seasonal Forecast Guidance for precipitation**
- **Executive Summary**

Current state of El Niño/Southern Oscillation (ENSO) phenomenon (bottom), compared to last month (top): Current SST anomalies are still consistent with developing El Niño conditions, but weaker than last month, and still not in the right sense for the wind department

Five-Day Mean Ending on June 16 2014

Multivariate ENSO Index (MEI) after neutral August-February periods since 1950 vs. recent conditions

Last seven years have seen two ‘double-dip’ Las Niñas in a row, followed by a brief excursion to what looked like an El Niño event in 2012, and a return to ENSO-neutral or weak La Niña conditions for much of the last year.

ENSO conditions often change during our spring season. This year towards El Niño indeed, in fact, this is one of the biggest one-month increases of the MEI on record. <http://www.esrl.noaa.gov/psd/enso/mei>

NINO3.4 SST anomaly plume
ECMWF forecast from 1 May 2014
Monthly mean anomalies relative to NCEP OIv2 1981-2010 climatology

The ECMWF May 2014 forecast (left) was the third one in a row to virtually guarantee a significant El Niño event, since only one of its 50 ensemble members dipped below 0° C through November 2014. In fact, the median value of +1.5° C in boreal fall was the highest of any model.

The ECMWF June 2014 forecast (right) is a bit slower to ramp up through the summer. The median peak value has dropped a little below +1.5° C, but it remains one of the most bullish ones within the IRI plume (*not shown, since not officially out yet*).

vs/

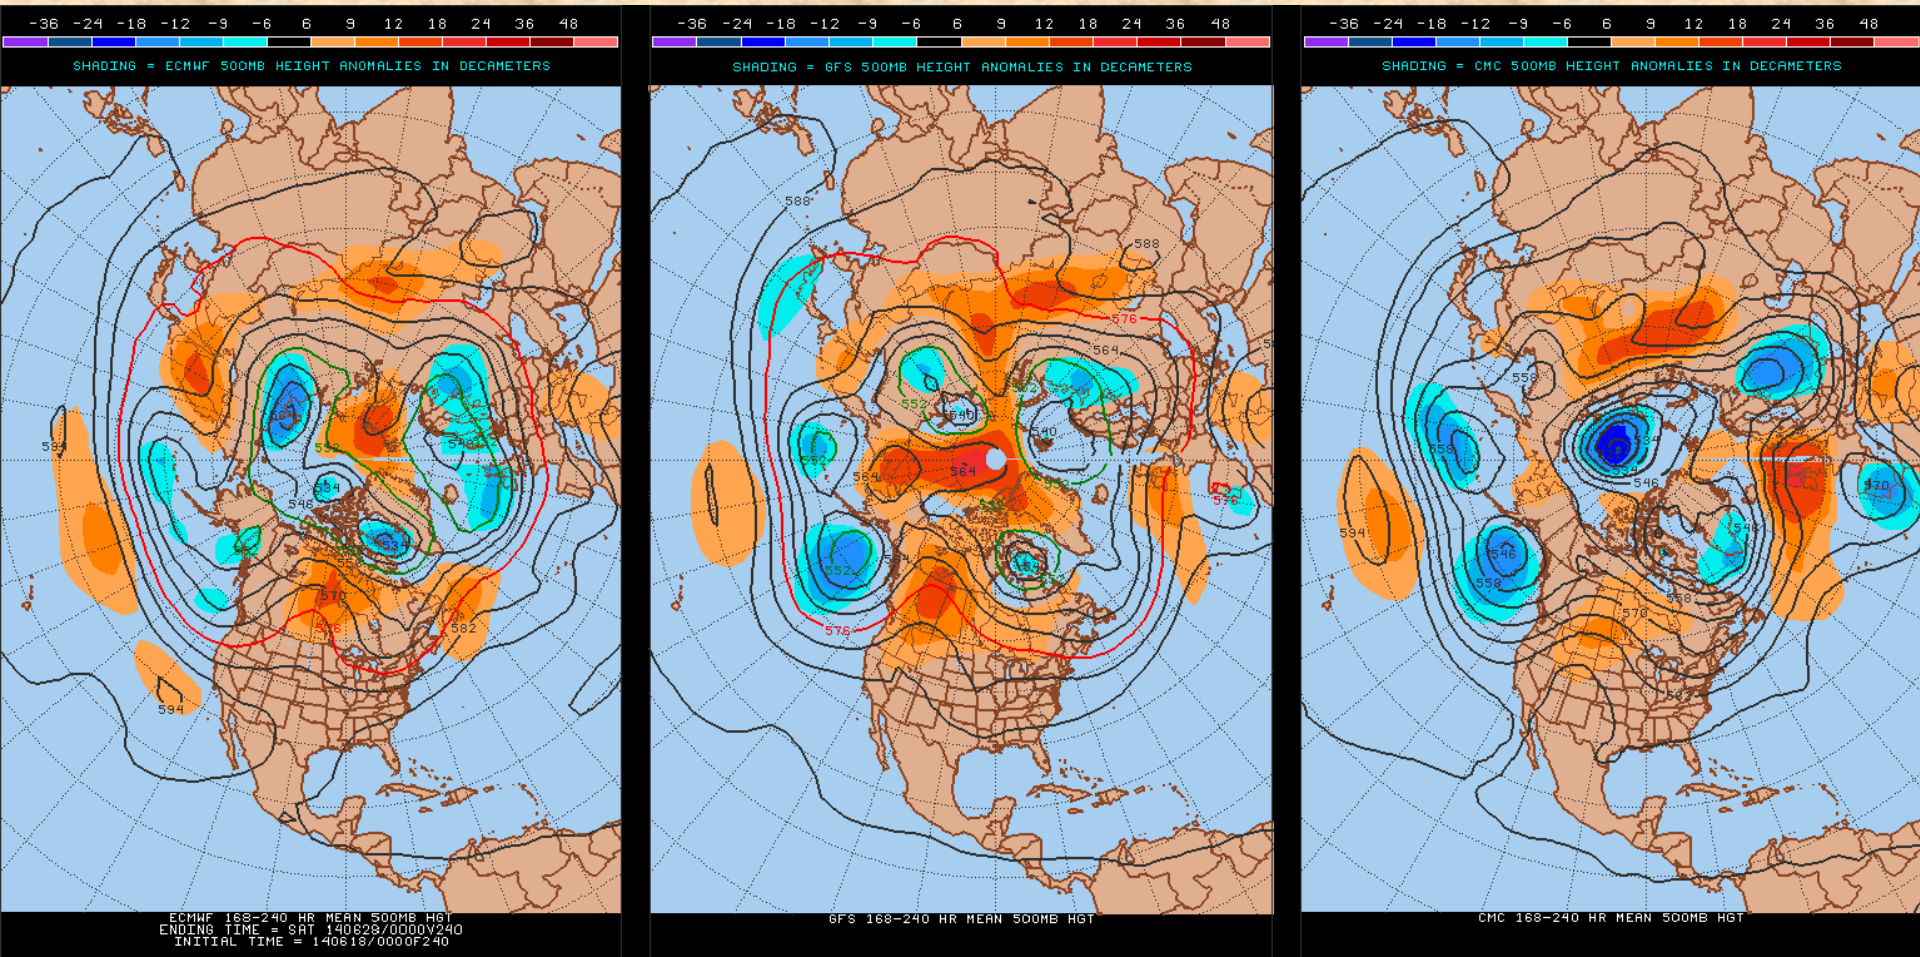

What can we expect in the next seven days?

Expected total precipitation (Hydrological Prediction Center, NOAA): a clear east-west gradient, consistent with climatology for this time of year, perhaps bringing some much needed moisture to SE CO, although the track record has been 'spotty'.

What can we expect later next week?

No major anomalies for us 7-10 days from now, with the overall pattern slowly drifting towards an early monsoon situation. At this time of year that should be associated with rising temperatures.

What do the 'Reforecasts' say?

000-168hr fcst from 00Z Wed Jun 18. Valid 00Z Wed Jun 18 - 00Z Wed Jun 25

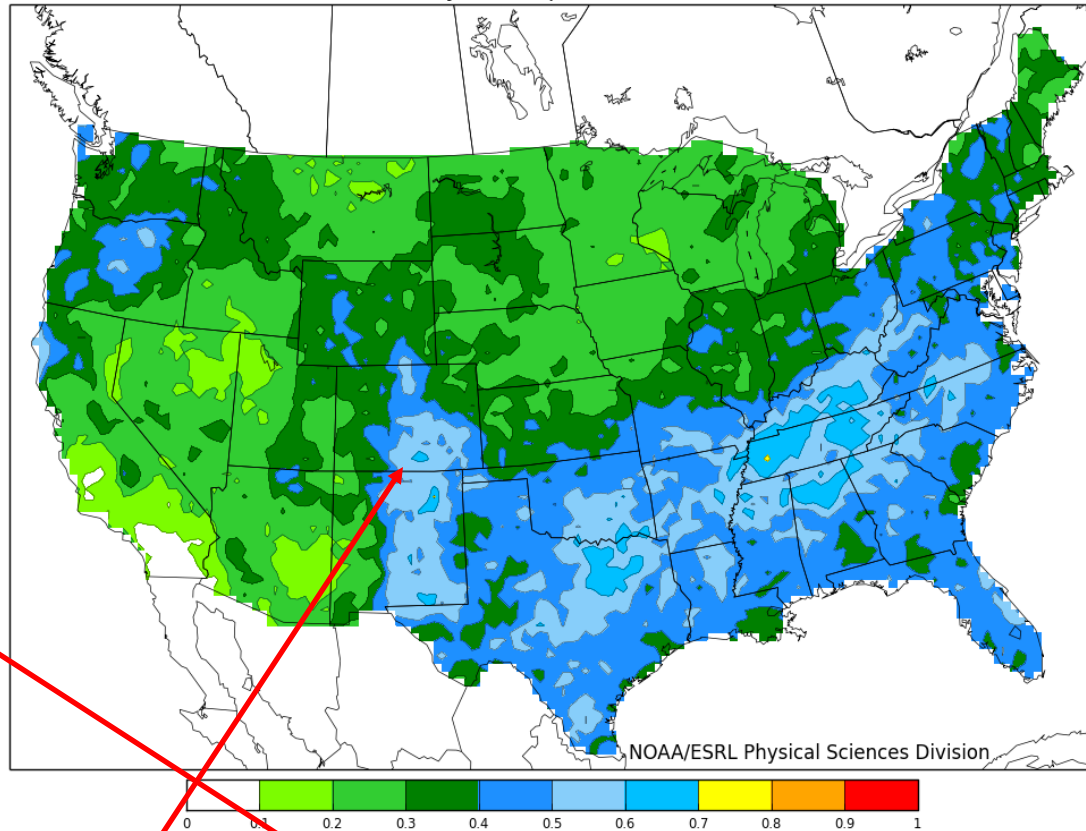

Calibrated with 1985-2010 Reforecast2 data.

Probability of Precip > 67th Percentile

168-336hr fcst from 00Z Wed Jun 18. Valid 00Z Wed Jun 25 - 00Z Wed Jul 02

Calibrated with 1985-2010 Reforecast2 data.

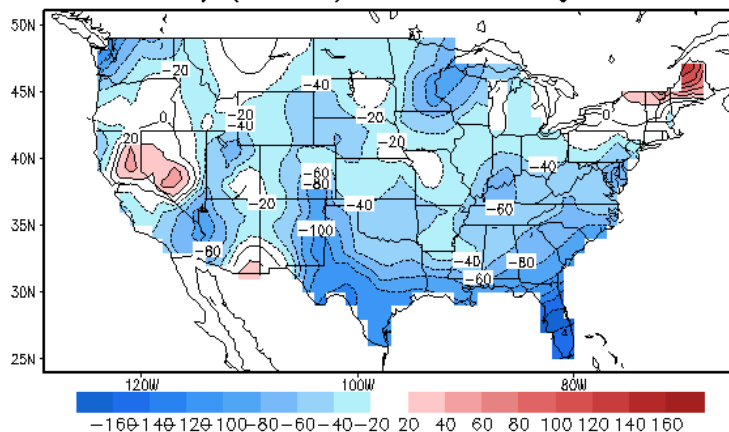

Probability of Precip > 67th Percentile

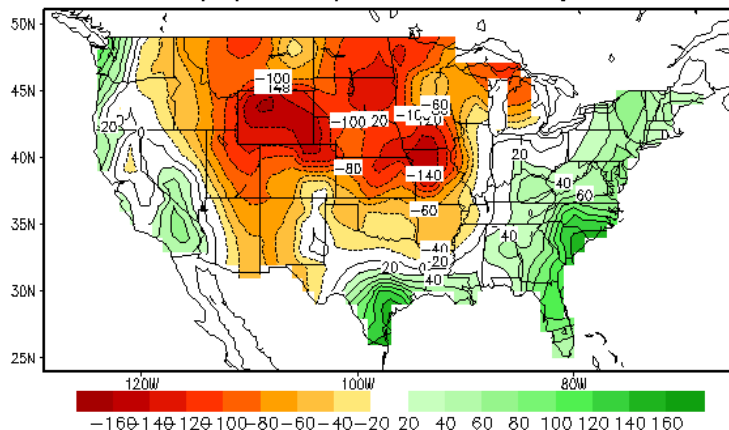

Next week looks dry for western CO and wet for the eastern plains (left), consistent with HPC, while the following week (right) broadens this to look more like an early (eastward shifted) monsoon pattern that could end up favoring SE CO in particular.

Soil Moisture Analogue Forecasts

Lagged Averaged Temperature Outlook for JAS 2014
units: anomaly (sdX100), SM data ending at 20140616

Lagged Averaged Precipitation Outlook for JAS 2014
units: anomaly (sdX100), SM data ending at 20140616

lead 1 skill of temperature CAS forecast for JAS
units: correlation (X100) based on 1981-2005

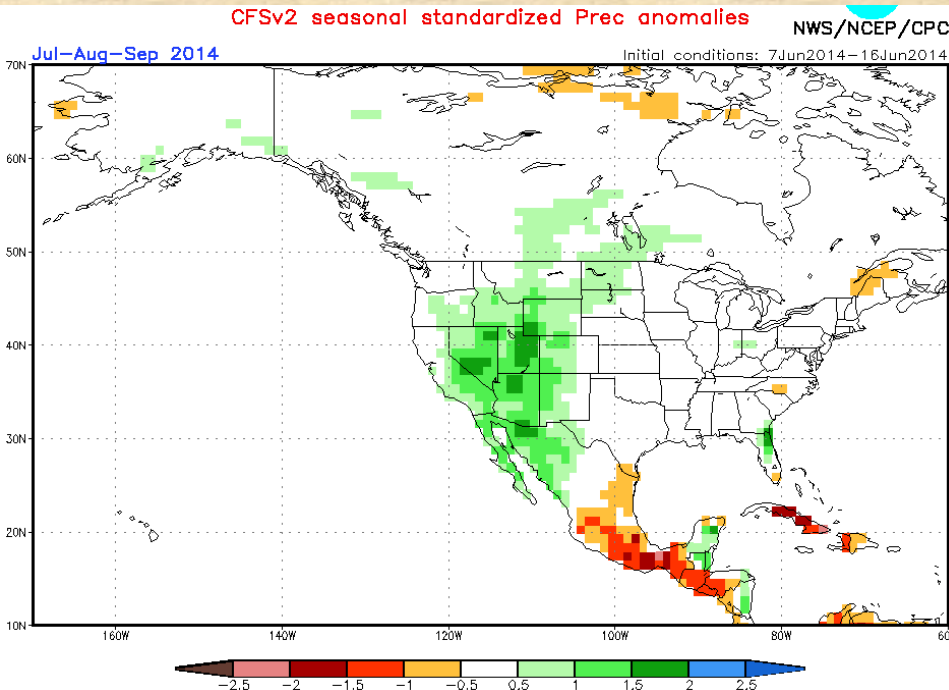

lead 1 skill of precipitation CAS forecast for JAS
units: correlation (X100) based on 1981-2005

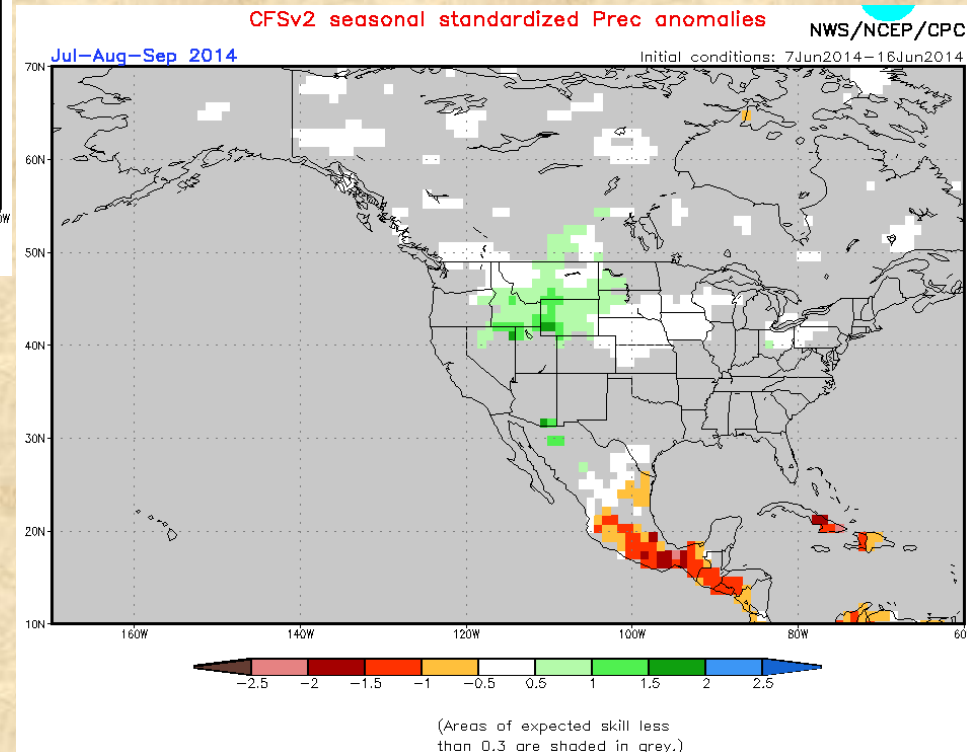

The soil moisture tool anticipates a mostly cool and dry monsoon season over our state, supported by historical skill (*and weak El Niño*).

Coupled Forecast System V.2 forecasts

<http://www.cpc.ncep.noaa.gov/products/predictions/90day/tools/briefing/>

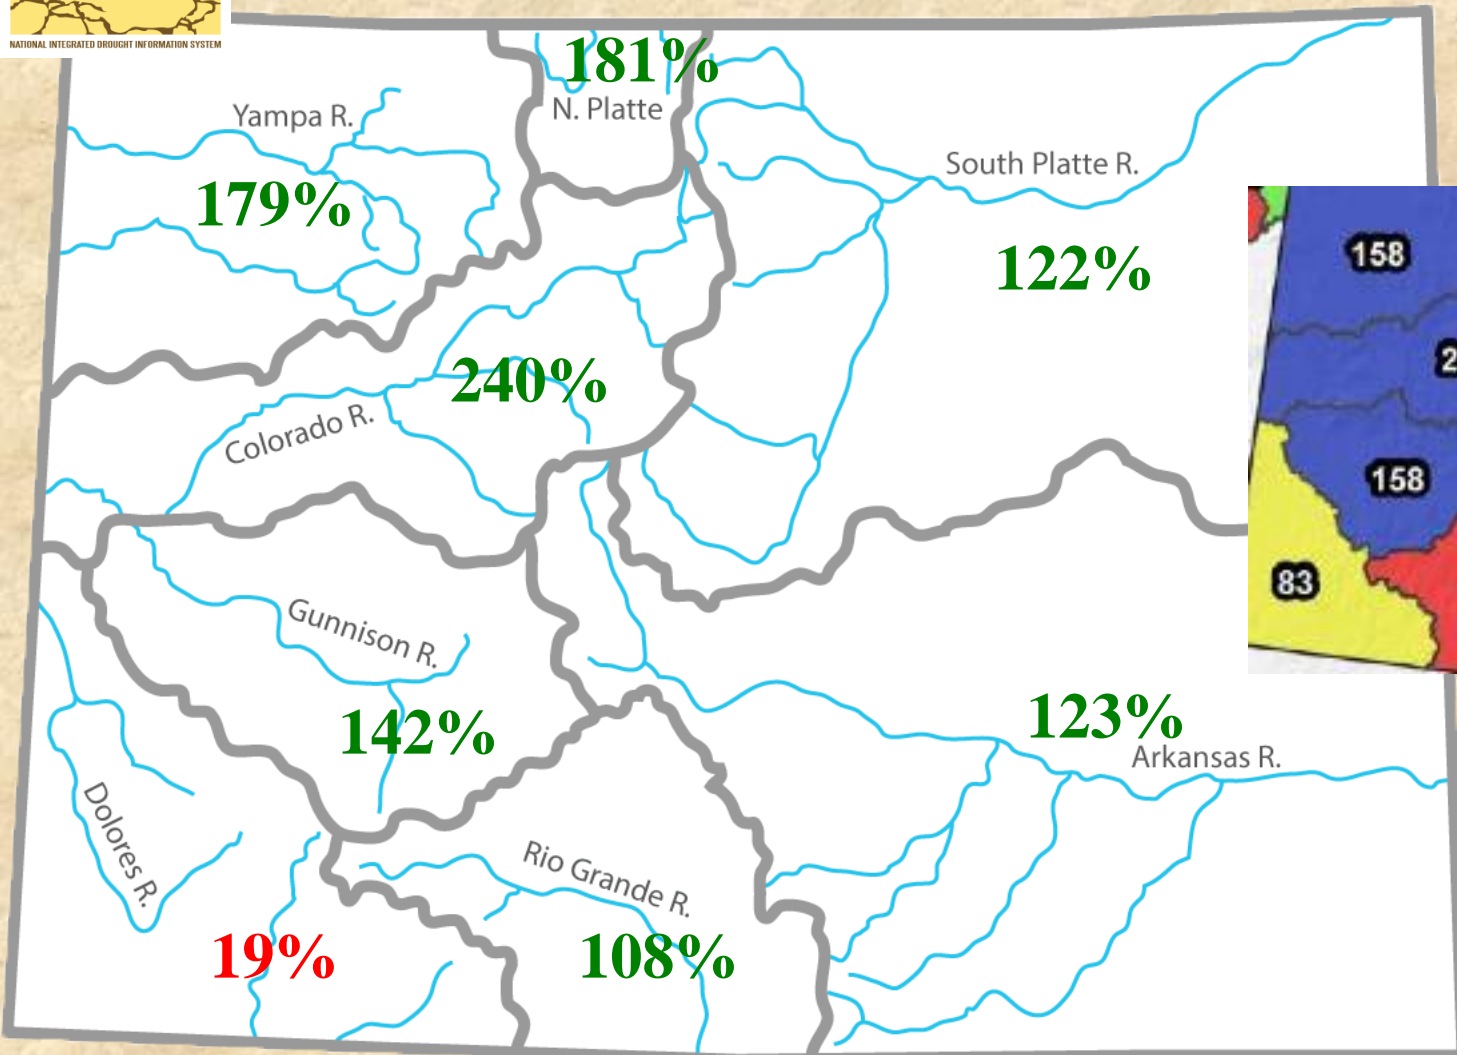

Climate Prediction Center Forecasts

Colorado is not likely to be warmer-than-average this summer according to CPC (left). Their moisture forecast is wetter-than-average for much of the interior western U.S. *This was driven by their coupled forecast model (CFS).*

SWE forecast for 1 June 2014 (50%ile)

My median forecast for 1 June snowpack from April was higher than the long-term median for most of the state. Perhaps 'beginner's luck', but the above 'normal' verified by May 29th (right insert), with the Rio Grande basin being the only basin really 'off'.

Experimental PSD Precipitation Forecast Guidance
APR – JUN 2014 (February 2014)

Experimental PSD Precipitation Forecast Guidance
APR – JUN 2014 (March 14, 2014)

Experimental PSD Precipitation Forecast Guidance
APR – JUN 2014 (April 11, 2014)

Percent of Normal Precipitation (%)
4/1/2014 – 6/16/2014

My forecasts for April-June 2014 from Feb' (left), Mar' (middle), and Apr' (top right) showed slightly increased chances for moisture in the southeastern half of CO, and less over much of the Upper Basin, but increasingly better news for the San Juans. Operational skill has been best over UT and CO.

So far, moisture has been spotty, with the dry forecast regions verifying better than the wetter ones.

Experimental PSD Precipitation Forecast Guidance
JUL – SEP 2014 (April 16, 2014)

Experimental PSD Precipitation Forecast Guidance
JUL – SEP 2014 (May 15, 2014)

Experimental PSD Precipitation Forecast Guidance
JUL – SEP 2014 (June 17, 2014)

My first seasonal forecast for July-September 2014 (left) was dry for much of the interior southwestern U.S., driest over AZ where El Niño often results in dry conditions during the summer. The May update (middle) remained surprisingly dry for much of the region, including the CO Front Range in particular. *My final update (right) reinforces this bleak picture which is consistent with a ‘weak El Niño’ scenario, sorry to say.*

- While El Niño/La Niña can provide decent guidance for climate outlooks around here, this was not very helpful in two years of ENSO-neutral conditions. El Niño has started, but is not firmly established yet. *The stronger this event gets, the more likely we will see a wetter growing season. In a similar vein, the recent switch in the Pacific Decadal Oscillation (PDO) – even if only temporary - appears to favor a wetter growing season as well.*
- My statistical forecast for late spring (April-June) showed a slight tilt towards wetness covering the eastern plains which has verified except for SE CO. The northwestern half of the state has not been as dry as expected. The monsoon season is forecast to end up dry for eastern CO and near-normal west of the divide. *This would be consistent with a weak El Niño which has indeed become more likely after the lack of coupling over the equatorial Pacific since May.*
- Given the rains of last September, an above-normal snowpack in the northern mountains, and a transition to El Niño, the stage was set for increased flood risk during the snow-melt season, and late May brought indeed some flooding, but all in all cool and drying weather at higher elevations ended up reducing that threat in June. *But we are not out of the woods yet, the peak of the monsoon season in late July in particular could still pose a flashflood threat, even if the season overall ends up dry.*
