East Fork Dry Creek Executive Summary

CWCB STAFF INSTREAM FLOW RECOMMENDATION January 27-28, 2025

UPPER TERMINUS:	headwaters in the vicinity of UTM North: 4245723.89 UTM East: 225416.86
LOWER TERMINUS:	confluence with Beaver Dams Creek at UTM North: 4246758.01 UTM East: 229778.94
WATER DIVISION/DISTRICT:	4/68
COUNTY:	Montrose, Ouray
WATERSHED:	Uncompahgre
CWCB ID:	21/4/A-004
RECOMMENDER:	Colorado Parks and Wildlife (CPW)
LENGTH:	3.11 miles
FLOW RECOMMENDATION:	0.6 cfs (11/01 - 02/29) 1.5 cfs (03/01 - 03/31) 2.5 cfs (04/01 - 07/31) 1.2 cfs (08/01 - 10/31)

**COLORADO** Colorado Water Conservation Board

Department of Natural Resources

#### BACKGROUND

Colorado's General Assembly created the Instream Flow and Natural Lake Level Program in 1973, recognizing "the need to correlate the activities of mankind with some reasonable preservation of the natural environment" (see 37-92-102 (3), C.R.S.). The statute vests the Colorado Water Conservation Board (CWCB or Board) with the exclusive authority to appropriate and acquire instream flow (ISF) and natural lake level (NLL) water rights. Before initiating a water right filing, the Board must determine that: 1) there is a natural environment that can be preserved to a reasonable degree with the Board's water right if granted, 2) the natural environment will be preserved to a reasonable degree by the water available for the appropriation to be made, and 3) such environment can exist without material injury to water rights.

The information contained in this Executive Summary and the associated supporting data and analyses form the basis for staff's ISF recommendation to be considered by the Board. This Executive Summary provides sufficient information to support the CWCB findings required by ISF Rule 5i on natural environment, water availability, and material injury. Additional supporting information is located at: <a href="https://cwcb.colorado.gov/2025-isf-recommendations">https://cwcb.colorado.gov/2025-isf-recommendations</a>.

#### RECOMMENDED ISF REACH

CPW recommended that the CWCB appropriate an ISF water right on a reach of East Fork Dry Creek at the ISF Workshop in January 2020. East Fork Dry Creek is located within Montrose and Ouray Counties and is approximately fifteen miles southwest of the City of Montrose (See Vicinity Map). The stream originates on the Uncompany Plateau and flows east until it reaches the confluence with Beaver Dams Creek. East Fork Dry Creek is a tributary to Dry Creek. A tributary to the Uncompany to the Uncompany to the Gunnison River.

The proposed ISF reach extends from headwaters downstream to the confluence with Beaver Dams Creek for a total of 3.11 miles. Approximately 45% of the proposed reach is on public lands managed under the Uncompany National Forest, the rest is on private land (See Land Ownership Map). CPW is interested in protecting this stream to preserve the natural environment which includes native Colorado River cutthroat trout.

#### OUTREACH

Stakeholder input is a valued part of the CWCB staff's analysis of ISF recommendations. Currently, more than 1,100 people subscribe to the ISF mailing list. Notice of the potential appropriation of an ISF water right on East Fork Dry Creek was sent to the mailing list in November 2024, March 2024, March 2023, March 2022, March 2021, and March 2020. Staff sent letters to identified landowners adjacent to East Fork Dry Creek based on information from the county assessor's website. Public notices about this recommendation were also published in the Montrose Daily Press on December 7, 2024 and the Ouray County Plaindealer on December 12, 2024.

Staff presented information about the ISF program and this recommendation to the Montrose and Ouray Boards of County Commissioners on 11/21/2022 and 10/08/2024, respectively. In addition, staff spoke with Eric Weig, District 68 Water Commissioner, on June 26, 2024 regarding water availability on East Fork Dry Creek. This conversation confirmed hydrologic and adminstatrative understanding of East Fork Dry Creek.

# NATURAL ENVIRONMENT

CWCB staff relies on the recommending entity to provide information about the natural environment. In addition, staff reviews information and conducts site visits for each recommended ISF appropriation. This information provides the Board with a basis for determining that a natural environment exists.

East Fork Dry Creek is a first order headwater stream which flows easterly off the Uncompany Plateau towards the town of Montrose. East Fork Dry Creek is a relatively high-gradient channel with substrate that ranges from small cobble to gravel and sand. Fish habitat in East Fork Dry Creek is complex and includes significant large woody debris in the channel creating deep pools. Log-jams are plentiful throughout the ISF reach which create both pools and long runs. These refuge habitats support fish when flows are periodically low following runoff. Ample overhead shading provides cover and temperature buffering. The creek also supports a healthy riparian area with willows and skunk cabbage observed in field as well as a diverse macroinvertebrate community including stonefly, case-making caddisfly, midges, and water beetle.

East Fork Dry Creek supports a self-sustaining population of Colorado River cutthroat trout of the Gunnison Basin lineage (Table 1). Colorado River cutthroat trout are a state species of special concern and considered a federally sensitive species (CPW, 2015). Length-frequency data indicates multiple age classes surveyed by CPW in 2017 (see Appendix), which reinforces that the cutthroat trout in East Fork Dry Creek are a self-sustaining population. Multiple cutthroat trout were observed during 2020 and 2022 site visits.

Species Name	Scientific Name	Status
Colorado River Cutthroat Trout- Gunnison Basin Lineage	Oncorhynchus clarkii pleuriticus	State - Species of Special Concern

## **ISF QUANTIFICATION**

CWCB staff relies on the biological expertise of the recommending entity to quantify the amount of water required to preserve the natural environment to a reasonable degree. CWCB staff performs a thorough review of the quantification analyses completed by the recommending entity to ensure consistency with accepted standards.

#### Quantification Methodology

CPW staff used the R2Cross method to develop the initial ISF recommendation. The R2Cross method is based on a hydraulic model and uses field data collected in a stream riffle (CWCB, 2022; CWCB, 2024). Riffles are the stream habitat type that are most vulnerable to dry if streamflow ceases. The data collected consists of a streamflow measurement, a survey of channel geometry and features at a cross-section, and a survey of the longitudinal slope of the water surface.

The R2Cross model uses Ferguson's Variable-Power Equation (VPE) to estimate roughness and hydraulic conditions at different water stages at the measured cross-section (Ferguson, 2007; Ferguson, 2021). This approach is based on calibrating the model as described in Ferguson (2021). The model is used to evaluate three hydraulic criteria: average depth, average velocity, and percent wetted perimeter. Maintaining these hydraulic parameters at adequate levels

across riffle habitat types also will maintain aquatic habitat in pools and runs for most life stages of fish and aquatic macroinvertebrates (Nehring, 1979). CPW staff use the model results to develop an initial recommendation for summer and winter flows. The summer flow recommendation is based on the flow that meets all three hydraulic criteria. The winter flow recommendation is based on the flow that meets two of the three hydraulic criteria.

The R2Cross method estimates the biological amount of water needed for summer and winter periods. The recommending entity uses the R2Cross results and its biological expertise to develop an initial ISF recommendation. CWCB staff then evaluates water availability for the reach typically based on median hydrology (see the Water Availability section below for more details). The water availability analysis may indicate less water is available than the initial recommendation. In that case, the recommending entity either modifies the magnitude and/or duration of the recommended ISF rates if the available flows will preserve the natural environment to a reasonable degree or withdraws the recommendation.

#### Data Collection and Analysis

CPW collected R2Cross data at one transect for this proposed ISF reach (Table 2 and Site Map). The R2Cross model results in a winter flow of 1.8 cfs and a summer flow of 2.5 cfs. R2Cross field data and model results can be found in the appendix to this report.

Table 2. Summary of R2Cross cross-section measurements and results for East Fork Dr	J
Creek.	

Date, XS #	Top Width (feet)	Streamflow (cfs)	Winter Rate (cfs)	Summer Rate (cfs)
05/26/2022, 1	14.48	1.49	1.84	2.54
			1.84	2.54

#### ISF Recommendation

CPW recommends the following flows based on R2Cross modeling analyses, biological expertise, and staff's water availability analysis.

0.60 cfs is recommended from November 1 to February 29; this flow rate has been reduced due to water availability limitations. This flow rate supports baseflows in the stream and will provide sufficient wetted perimeter and refuge habitat in deep pools and glides, especially those holding habitats created from large woody debris in the channel.

1.5 cfs is recommended from March 1 to March 31; this flow rate has been reduced due to water availability limitations. This flow rate will support sufficient wetted perimeter and depth as fish transition to more metabolic activity as they come out of overwintering conditions.

2.5 cfs is recommended from April 1 to July 31 and meets all three hydraulic criteria for summer flows. This flow rate will support fish when they are most active and will provide refuge areas when stream temperatures are high following spring runoff. This higher flow rate also supports beneficial spawning conditions for cutthroat trout who spawn in the spring to early summer. It will also allow for streamflow conditions which support feeding and growth.

1.2 cfs is recommended from August 1 to October 31; this flow rate has been reduced due to water availability limitations. This flow rate follows the falling limb of the streams hydrograph will provide sufficient wetted perimeter and habitat availability in pools and glides and may allow fish movement between most riffles.

## WATER AVAILABILITY

CWCB staff conducts hydrologic analyses for each recommended ISF appropriation to provide the Board with a basis for determining that water is available.

#### Water Availability Methodology

Each recommended ISF reach has a unique flow regime that depends on variables such as the timing, magnitude, and location of water inputs (such as rain, snow, and snowmelt) and water losses (such as diversions, reservoirs, evaporation and transpiration, groundwater recharge, etc.). This approach focuses on streamflow and the influence of flow alterations, such as diversions, to understand how much water is physically available in the recommended reach.

Staff's hydrologic analysis is data-driven, meaning that staff gathers and evaluates the best available data and uses the best available analysis method for that data. Whenever possible, long-term stream gage data (period of record 20 or more years) are used to evaluate streamflow. Other streamflow information such as short-term gages, temporary gages, spot streamflow measurements, diversion records, and regression-based models are used when long-term gage data is not available. CSUFlow18 is a multiple regression model developed by Colorado State University researchers using streamflow gage data collected between 2001 and 2018 (Eurich et al., 2021). This model estimates mean-monthly streamflow based on drainage basin area, basin terrain variables, and average basin precipitation and snow persistence. Diversion records are used to evaluate the effect of surface water diversions when necessary. Interviews with water commissioners, landowners, and ditch or reservoir operators can provide additional information. A range of analytical techniques may be employed to extend gage records, estimate streamflow in ungaged locations, and estimate the effects of diversions. The goal is to obtain the most detailed and reliable estimate of hydrology using the most efficient analysis technique.

The final product of the hydrologic analysis used to determine water availability is a hydrograph, which shows streamflow and the proposed ISF rate over the course of one year. The hydrograph will show median daily values when daily data is available from gage records; otherwise, it will present mean-monthly streamflow values. Staff will calculate 95% confidence intervals for the median streamflow if there is sufficient data. Statistically, there is 95% confidence that the true value of the median streamflow is located within the confidence interval.

#### **Basin Characteristics**

The contributing basin of the proposed ISF on East Fork Dry Creek is 5.7 square miles, with an average elevation of 9,291 feet and average annual precipitation of 23.2 inches. East Fork Dry Creek is a high elevation, steep gradient, snowmelt driven hydrologic system. The basin has natural streamflow conditions and is anthropogenically unaltered.

#### Water Rights Assessment

There are no diversions within the reach of East Fork Dry Creek recommended for an ISF. The lower terminus of the recommended reach is located at the upper terminus of an existing ISF on East Fork Dry Creek decreed in 05CW0151.

#### Data Collection and Analysis

#### Representative Gage Analysis

There are no current or historic gages on East Fork Dry Creek. Staff investigated nearby gages for similarities in basin characteristics and hydrology and found no gages were sufficiently similar to be used to estimate streamflow on East Fork Dry Creek.

#### Multiple Regression Model

The CSUFlow18 regression model predicts mean-monthly flow in East Fork Dry Creek and provides the best estimate for streamflow conditions.

#### Site Visit Data

CWCB staff joined CPW on a site visit during data collection for R2Cross modeling on 5/26/2022.

#### Water Availability Summary

The hydrograph shows CSUFlow18 results for mean-monthly streamflow and includes the proposed ISF rate (See Complete Hydrograph). The proposed ISF flow rate is below the mean-monthly streamflow. Staff concludes that water is available for appropriation on East Fork Dry Creek.

#### **MATERIAL INJURY**

If decreed, the proposed ISF on East Fork Dry Creek would be a new junior water right. This ISF water right can exist without material injury to other senior water rights. Under the provisions of section 37-92-102(3)(b), C.R.S., the CWCB will recognize any uses or exchanges of water in existence on the date this ISF water right is appropriated.

### ADDITIONAL INFORMATION
