RE: New Horizon Mine (Permit No. C-1981-008)
Technical Revision No. 101 (TR-101)
Water Monitoring Program Revision

Dear Mrs. Binns:

Tri-State Generation and Transmission Association Inc. (Tri-State), is the parent company to Elk Ridge Mining and Reclamation, LCC (ERMR), which owns and operates New Horizon Mine. The New Horizon Mine operates under the Division of Reclamation, Mining and Safety (DRMS) Permit No. C-1981-008. Therefore, Tri-State on behalf of ERMR is submitting TR-101, which proposes modifications to the water-monitoring program for the New Horizon Mine.

Under TR-101, Tri-State is proposing several modifications to the water-monitoring program. The Division will probably request a hydrology demonstration to support these proposed changes to the water-monitoring program. However, the annual hydrology report was just submitted at the end of December 2020, which contains the applicable data set that would be used to compile and submit another hydrology demonstration to the Division. It would be appreciated if the Division would reference the annual hydrology report submitted on December 21, 2020 for data associated with the wells and surface water-monitoring site proposed to be revised under this technical revision.

The monitoring locations proposed to be relinquished and a short justification for each, are described in more detail below. The locations of these monitoring sites can also be found on Map 2.04.7-1A in Permit No. C-1981-008.

Groundwater Wells

Wells GW-N16P1, GW-N17P1, and GW-N18P1 are located on the southern boundary of Phase III released areas. The Division has also terminated jurisdiction in these areas, and the properties have been returned back to the surface landowner. Ground water flow in the backfill is north to northwest towards the northwestern corner of the permit boundary (ERMR Johnson Property); therefore, groundwater flowing through the backfill of Phase III release areas is flowing away from this series of wells. The only remaining disturbance that might be considered for this series of wells is 2.9 acres of a reclaimed haul road, and which is not a mined area. Moreover, the Division has already reviewed hydrologic impact analysis as it pertains to this series of wells when it granted Phase III bond and eventually terminated jurisdiction. Given the fact that all mined and backfilled areas directly adjacent to these wells has been Phase III released, the Division agreed with the hydrologic impact analysis submitted in the Phase III

January 25, 2021

Page 2

applications and the Division has terminated its jurisdiction, it is appropriate at this time to release this series of wells from the ground water monitoring program.

New Horizon has two series of up gradient wells, which includes well series GW-N41, GW-N42, GW-N43, and well series GW-N36, GW-N37, and GW-N38. Tri-State contends given the vast amount of Phase III bond release at New Horizon, and the fact that the Division has terminated jurisdiction upon, there is not a need to have two series of up gradient monitoring wells for New Horizon. That being said, Tri-State would like to propose relinquishing the monitoring requirements for wells GW-N41, GW-N42, and GW-N43, and New Horizon will continue monitoring GW-N36, GW-N37, and GW-N38 as up gradient wells.

Well GW-N3 is completed into the old Peabody Mine backfill (pre-law mining area north of New Horizon). This well does not have any hydrologic connectivity to the New Horizon mining or reclamation areas, and represents water quality from a pre-law mining area. It is not appropriate for the New Horizon to be monitoring a well that the data acquired from it is not representative of the site, not hydrologically connect to New Horizon, and provides data from another mining operation that pre-dates New Horizon. Therefore, Tri-State proposes to relinquish monitoring of this well.

Should the Division agree with Tri-State's proposal to relinquish monitoring the above-mentioned wells, they will promptly be property plugged and abandoned as required.

Surface Water Monitoring – Irrigation Water

Surface water site SW-N104 is on the Colorado Cooperative Company (CCC) Ditch. It is on the open ditch segment before the irrigation water enters the loading box and the CCC West Lateral Pipeline. New Horizon does not have any control of the quality of water delivered by the CCC Ditch Company, and the water delivered and associated quality is utilized by all waters users connected to the CCC Ditch regardless of the quality of water delivered. There is a robust data set acquired from monitoring this location over the years, and if the data was needed for an evaluation of revegetation success or other reasons it is available. Tri-State believes there is not any additional value to continue monitoring this location when it cannot control the water quality delivered, nor does continued monitoring provide any additional evaluations of potential mining related impacts. Revegetation success at New Horizon for irrigated pastures areas is tied to proper management of the irrigated pastures from the application of water and fertilizers, where appropriate, versus the water quality being delivered by the CCC Ditch Company.

Tri-State looks forward to continuing this discussion with the Division as it relates to the water-monitoring program for the New Horizon Mine. If you have any questions about the enclosed technical revision or require additional information on this proposal, please contact Tony Tennyson at (970) 326-3560 or ttennyson@tristategt.org.

two sample sets collected at each surface water site. In addition, Peabody collected water quality samples in April and October of 1987 at two points on the San Miguel River; 1) upstream of the confluence with Calamity Draw (San Miguel #2); and 2) downstream of the confluence with Tuttle Draw (San Miguel #1). The results of each silver and chromium analyses performed at each surface water monitoring site can be found in Attachment 2.04.7-11 (Peabody Appendix 7-9). The results of the additional analyses for silver and chromium showed that total recoverable chromium never exceeded 10 ug/l; and that silver exceeded 10 ug/l once each (20 ug/l at sites SW-N3 and SW-N7). Compared to standards adopted for the nearest applicable reach of the San Miguel River (Segment 5), all analyses for chromium (total recoverable) were well below the standard (25 ug/l). Unfortunately, the detection limit used by the laboratory for silver (total recoverable) was 10 ug/l, significantly higher than the standard (.1 ug/l).

With respect to Colorado Department of Health (CDOH) receiving stream standards (CDOH, 1983, revised 1986), Tuttle and Calamity Draws lie within the Stream Segment 12 of Region 10 of the San Miguel River. Because the listed parameters (physical and biological, only) are not applicable to both Tuttle and Calamity Draws, the nearest segment (downstream) in which applicable standards have been promulgated (Segment 5) are used to compare surface water quality of Calamity (SW-N103) and Tuttle Draws (SW-N3, NPDES 001 and NPDES 006).

Exceedences were observed at three sites: 1) iron at San Miguel #1 (downstream of Turtle Draw); 2) zinc and manganese at SW-N103; and 3) nickel at NPDES 006.

Based on the rigorous comparisons made, it is evident that water delivered by the West Lateral Irrigation Ditch is of sufficient quality for drinking water, agricultural use and livestock drinking water. This water originates from the San Miguel River upstream of Naturita, and is currently the primary source of water in the vicinity for the previously mentioned uses. Surface water in Calamity and Tuttle Draws, as well as the monitored tributaries, is not suitable for use as a source of drinking water. New Horizon has knowledge of irrigation being conducted using water from Calamity (Mr. Mel Statts, south of New Horizon Permit Boundary and bordering Calamity Draw). However, all surface water monitored at sites established in the New Horizon 2 area fall into suitability criteria for livestock drinking water and irrigation. Livestock and wildlife commonly use Calamity and Tuttle Draws as sources of drinking water. As long as the Colorado Co-operative Company continues to operate the ditch system, there will remain a sufficient supply of water well suited for domestic (drinking), agricultural and livestock use.

Hydrological Monitoring Program

New Horizon will report discharges associated with its CDPS permit (sediment pond discharges) in accordance with the Clean Water Act of 1977 on a quarterly basis to the Colorado Department of Public Health and Environment. Surface water and groundwater monitoring data (monitoring locations listed in the tables below) is reported to the Division in an annual hydrology report. Annual hydrologic reports for the period of October through September of the following year will be submitted to the Division by December 31 of each year.

New Horizon monitors the following sites:

Sedimentation Ponds – Discharges associated with the sediment ponds will be monitored as required under New Horizon’s CDPS Permit which is issued by the Colorado Department of Public Health and Environment. New Horizon will measure the quantity and quality of discharges from the permit area in compliance with the CDPS permit requirements. A copy of New Horizon’s CDPS permit is available onsite for review as necessary.

Surface Water - Surface water sites will be monitored for the New Horizon mine at locations along Calamity Draw and Tuttle Draw.

Monitoring Type	Monitoring Location	Monitoring Frequency	<u>Quarterly Field Parameters</u>	<u>Quarterly Laboratory Parameters</u>
Surface Water	SW-N103	Quarterly	See List Below.	See List Below.
Surface Water	SW-N108	Quarterly	See List Below	See List Below.

Probable Hydrological Consequences

A discussion of the probable hydrologic consequences and reclamation plan are contained in Section 2.05.6(3) and Section 2.05.6(3)(b)(v) of the permit application document. The following discussion is intended to supplement the description of potential impacts of mining and mitigation of these potential effects. The determination of significance has been made considering the impact on the quality of the human environment, existing water uses, and the intended post mining land use of the area.

Interruption of Groundwater Flow and Drawdown

In order to develop the impact assessment for groundwater quantity, two different analyses techniques were utilized. First, pit inflow volumes were determined on an annual basis using an analytical approach developed by McWhorter, 1982. The second analysis involved the determination of annual pit inflow rates and annual drawdowns in the adjacent overburden and coal aquifers as a result of the pit inflows. This analysis utilized the USGS 3-dimensional finite-difference groundwater flow model MODFLOW.

Transient simulations were performed for a five-year period, using the maximum drawdown estimates for the overburden and coal. These drawdown results are expressed as a maximum at the pit and are expressed as a conical depression which results in decreased drawdown at further distance from the mine. For the overburden, the pit drawdown was 5 feet for years 1 and 2, 8 feet during year 3, 15 feet during year 4, and 30 feet during year 5. The drawdown for the coal simulation was 8 feet during year 1, 5.8 feet during year 2, 6 feet during year 3, 7.3 feet during year 4, and 8 feet during year 5. The zero impact contour for the overburden and coal after five years of mining is approximately 4,000 feet. The overburden and coal drawdown contours do not intersect any of the boundaries, therefore, no impact of the San Miguel River from drawdown in the deeper part of the overburden or coal is predicted. Shallow aquifer flow into Tuttle and Calamity Draws in the vicinity of the pit will be decreased, but will be offset by pumpage from the pit. Simulated average daily pit inflow for the coal and overburden aquifers varied from 1,255 cubic feet per day in year 1 to 5,604 cubic feet per day in year 5. New Horizon's approach to these potential impacts is to monitor the aquifers and discharge from the pit to determine the extent of drawdown. The hydrological monitoring program should provide reasonably accurate measurements of effects of mining. Should the monitoring show that impacts to the groundwater aquifers are precluding its use, New Horizon will provide alternate water sources of comparable quantity and quality. As described in the water augmentation plan, New Horizon has a 114 acre foot consumptive use right on the Highline Canal which would be used to mitigate the potential 26 acre foot impact on surface water right users from pit inflow drawdown.

Impact on Groundwater Rights

No surface or groundwater rights have been identified within the New Horizon 2 mine area. Therefore, there will be no direct impact from the approved mining plan on any local water rights.

Impact of Spoil Material on Groundwater Flow and Recharge

The mine pit will remain open only until the coal has been removed. Following the short-term water level decline on the groundwater system as a result of pumpage of groundwater inflow to the pit, a potential long-term impact to the local groundwater flow is the period of time necessary for resaturation of the spoil material and reestablishment of a flow gradient. Spoil material at the New Horizon 2 mine will be replaced using techniques which will restore permeabilities of the material. Thus, the mining operation will not diminish vertical or horizontal permeabilities but may increase these permeabilities. As a result, there should be no significant impacts from the mining operation on groundwater flow and recharge rates. The time period required for the spoil material to resaturate should be greatly reduced because of the irrigation recharge as the mined area will be revegetated for an irrigation type of post mining land use.

Containment of Pit Inflow and Impacts on Water Quality

All runoff and pit pumpage from disturbed areas will be routed through sedimentation pond 007. The pond is designed and constructed to impound runoff and pit pumpage from areas disturbed by mining and provide sufficient residence time to insure that the pond discharge water chemistry meets the effluent requirements specified in the NPDES Permit. A review of the chemical and flow data indicates that the potential for any discharge from Pond 007 to exceed receiving stream or federal standards is minimal. Past history of mine operations at the Nucla Mine indicate very few exceedances of the standards over the years of operations. As previously discussed, highest pit inflow is predicted to occur in year 5 at approximately 5,600 cubic feet per day. To assess the impact of this inflow on Calamity Draw and the San Miguel water quality, it was assumed that the entire flow was discharged and that the TDS level for the overburden aquifer was representative of the chemical load. The duration of the water quality impacts is relatively short term (5 years) and the significance of the impact is negligible as TDS increases in the range of 0.08 to 1.5 percent are projected on the San Miguel River and Calamity Draw, respectively. These increases in TDS will be additional magnesium/sodium-sulfate type water which may result in a slight increase in salinity. These projected changes in TDS levels will in no way affect the present and potential uses of the surface water and are so small that they may not be measurable.

Impact of Spoil Water Quality on the Ground and Surface Water Quality

The available data indicate that a small proportion of the overburden may produce acid through the oxidation of pyrite. Based on laboratory tests on overburden cores, calcite is almost ubiquitous. Calcite serves two functions. First, it buffers the pH of the water, which overall tends to slow the oxidation of pyrite, slowing the production of acid. Second, it will neutralize the acid that is produced. The core samples that exhibited low paste pH's are surrounded by non-acid producing, calcite-bearing rocks. The water that contacts the low-paste pH materials will have first reacted with calcite, and therefore developed a pH-buffer capacity of its own. The groundwater monitoring data indicate that mixed overburden and interburden waters have near neutral pH's.

Sample pH's less than 6 are associated only with the lower Dakota coal. Where the coal's permeability is high enough to produce about 5 gpm during sampling, the acid-producing reactions do not appear to be fast enough to maintain the pH of the water less than 5. Oxidation rates may increase because of the mining process. However, the supply of oxidation is only one of the constraints on the production of acid. Other constraints are imposed by the quantity of calcite present, and the reactivity of the pyrite. The paste-pH test, conducted under oxidizing conditions, indicates that a very small proportion of the overburden is likely to produce acid. The acid that is produced will be quickly neutralized. During the mining process, New Horizon will test the overburden and if acidic layers are encountered, they will be mixed with non-acidic layers to neutralize any acid forming effects.

Potential Impacts of Replaced Spoil on Groundwater Quality

The analysis of geochemical controls on groundwater quality suggests that the water chemistry and concentrations of most elements of concern are controlled by mineralogic reactions that will resist changes in water chemistry. Production of acid may occur in very local settings and is probably most prevalent in the coal, which will be mined. Calculations indicate that neutralization of the acid will occur rapidly with mixing of water, or with movement of acidic water into calcite-bearing rocks. Also, the analysis conducted indicates that chemical changes are not likely to occur.

Effects of Mining on the Local Geomorphology

Impacts from mining on the local geomorphology will be long term, but appear to be of minimal significance. The reestablished reach of the drainage which will be mined will result in a shorter, slightly steeper stream channel. The potential for increased sediment loads in the drainage (once pond 007 is removed) should be offset by the stable banksides and the relatively small change in overall gradient. The increased runoff and consequent erosion potential on disturbed basins in the mining area due to the temporary loss of topsoil structure should be of minimal significance. Contour ripping, mulching and revegetation have been demonstrated to minimize soil erosion and will be used to mitigate the increased runoff potential until the topsoil structure is developed.

Effects of Sediment Ponds on Channel Characteristics and Downstream Users

Potential impacts of sediment pond 007 on downstream users will involve possible reductions in flow due to impounded water. The water augmentation plan discusses the available water which will be used should impacts be identified. New Horizon currently has rights to a sufficient quantity of water to supply all users associated with the mining activities, plus an additional quantity of water that can be used to mitigate any impact to downstream users.

Effects of Sediment Pond Discharge on Surface Water Quality

The effects of sediment pond diversions on surface water quality will be negligible because the

structure has been designed to minimize impacts to the hydrologic balance. The diversion involves such minor areas of disturbance that chemical and sediment changes in the flows will be unmeasurable.

Effects of Runoff from Reclaimed Areas on the Quality of Streamflow

Due to the relatively small area of disturbance in the New Horizon 2 mining area, any reductions in runoff will have only a minimal impact on streamflow quantity, as flow in Calamity Draw is dominated by irrigation return flow. Decreased sediment loads predicated by SEDCAD+ indicate that reclamation efforts conducted in the mining area will ensure that additional contributions of suspended sediment in runoff from reclaimed areas will not occur. Effects of runoff from reclaimed areas on the quality of streamflow. Based on past operating history at the Nucla Mine, no significant trend toward higher concentrations of the selected parameters have been detected. In addition, the pond discharge will be monitored in accordance with NPDES discharge limitations and any potential impact will be identified. Therefore, runoff from the reclaimed area should have no significant impact over time on the quality of receiving stream water quality. As a result, post mining land uses which currently occur in the area should not be affected due to the mine plan which has been approved.

Summary

The discussion presented herein of the probable hydrologic consequences of the revised mine plan approved by New Horizon identifies the potential effects of mining. Table 2.05.6(3)-1 summarizes the discussion by listing the probable hydrologic consequences and the results of the analysis of each. As can be seen, all of the probable impacts have been determined to be of a short term nature, of minimal significance, or a plan has been presented to mitigate those determined to have some significance. As a result, mining and post mining affects to current land uses should be negligible.

Map 2.04.7-1A has been updated to differentiate between active and non-active wells. They are also marked with their current status. They have been distinguished by both color and symbol. Attachment 2.04.7-2 has the lithologic logs for wells GW-N41 through GW-N46. A new attachment titled Attachment 2.04.7-4 to display the current status and baseline data of all ground water wells of both New Horizon #1 and #2 Mines has been created to include data for all wells. Since the N41 through 46 hole logs were slightly different, it was decided to keep this attachment.
