2020 Annual Hydrology Report for Trapper Mine
Year End Review

A. Climatological Data

The 2020 National Weather Service Cooperative monthly summaries and the historical precipitation summary (1978-2020) are included in Section 2.5. For the year of 2020 precipitation totaled 13.47", providing 99 percent of the established historical pre-mining (44-YR) annual precipitation mean and 82 percent of the project-to-date annual precipitation mean (Figure 2-1). The highest monthly precipitation amount was recorded in January (1.84") with the second and third highest totals occurring in March and February (1.81" and 1.47", respectively). Conversely the lowest monthly precipitations occurred in September, November and August at 0.35", 0.52" and 0.54".

B. Pit Dewatering and Consumptive Water Use for 2020

During 2020, Trapper dewatered approximately 12.73 acre-feet of water from L-Pit and 32.79 acre-feet of water from G-Pit and N-Pit dewatering wells. (Table 1-1 of Section 2.5 sub-section 1.0 shows the pumping volumes for each activity). The dewatering wells are expected to produce at approximately the same rates for 2021. All pit water was routed into the NPDES drainage system with resulting discharges monitored accordingly when pumped off site. In 2020, all of the pumped water was utilized on haulroads for dust suppression.

Approximately 223.46 acre-feet of water was used for dust suppression on haul roads and topsoil handling operations in 2020. This value increased slightly this year compared to last year but is around the average from the past few years. The majority of this water was utilized from A-Pit where water has been stored in the inactive pit. Dust suppression water demands continue to be offset by the successful application of dust suppression chemical treatments on haulroads. Haul routes were similar in 2020 to 2019 routes. Life-of-mine Haulroad is still the primary route for coal delivery to the Craig Station. Continued activity in the eastern portion of the mine accounts for the majority of dust suppression water usage. Total water volume used by Trapper Mine in 2020 was approximately 269 acre-feet, a slight decrease over 2019 consumption at 247 acre feet.

C. Mining Advancement and Ash Disposal Sites

The 2020 Annual Reclamation maps (see Trapper's 2020 annual report), the Water-Level Elevation maps 2-1, 2-2 and 2-3 (included in this report), and permit Map M52 (see mine permit) depict the following mining activities through year-end:

a) Project to date utility waste disposal sites.
b) Project to date pit advancement (toe of pit).
c) Project to date monitoring wells, and natural and spoil springs and seeps. In the 2020 report, all applicable spring and seep sites within the permit area are depicted to provide location information for future reference.

D. Monitoring Points

Refer to Map M52 in the mine permit for locations of all the operational hydrologic monitoring points.

E. 2020 Hydrological Data

Hydro-Engineering Inc.'s collation of the 2020 hydrological data for Trapper Mine is submitted following this discussion, and addresses:

a. Groundwater ..... Sections 2.0-3.6
   (1) Groundwater level figures and tables ..... Appendix A
   (2) Groundwater quality figures and tables ..... Appendix B
   (3) Piezometric surface maps for the major aquifers ..... Maps 2-1 thru 2-3
   (4) Springs data ..... Appendix B

b. Surface water ..... Sections 4.0-5.3
   (1) Surface-water quality figures and tables ..... Appendix C
   (2) Flow measurement figures ..... Appendix C
   (3) Flow vs TSS vs time figures ..... Appendix C
   (4) Conductivity vs flow vs time figures ..... Appendix C

c. Observed impacts on the hydrologic systems ..... Section 6.0

Included with the 2020 Hydrology Report is an index sheet to keep the basic well data and aquifer information available to the reader. This index may be used as a reference and also a "bookmark" as the section is reviewed.

F. Trends

Hydro-Engineering's Section 6.0 discusses the observed impacts on the hydrologic systems of Trapper Mine. Four surface water monitoring sites experienced discharge during 2020. Peak flows occurred at most sites in early April. Significant snowpack remained on the site until mid-March when warmer temperatures reduced it to nearly zero by the end of the month at lower elevations. Snowmelt was slower at the higher elevations lingering well into April. Runoff from the site was moderate due to unfrozen soils and good infiltration. The late spring precipitation was below average in April and May with the months of June and July resulting in average rainfall. August through November were significantly dry. Hydro-Engineering's Section 6.0 discussion provides details concerning 2020 trends. Overall, Trapper continues to have little effect on the local hydrologic regime.

G. Spring Sampling (2020)

Trapper conducted spring sampling throughout the permit area during 2020. Data from this monitoring is presented in the 2020 Annual Hydrology Report Appendix B Table B-2. Spring and Seep locations are shown on Map M52 in the mine permit. Only those springs with flows exceeding 5 gpm are sampled for full suite analysis in accordance with the approved monitoring program.

H. WET Testing Results

In 2020, no NPDES outfall had Acute WET tests performed as required by NPDES Permit CO-0032115. In accordance with our NPDES permit only those drainages that receive pit dewatering or spoil spring contributions are required to undergo WET testing. Pit de-watering discharges did not pass through any active outfall and all potential spoil springs on the site have been bond released and no longer require monitoring.

APPENDIX C SURFACE-WATER QUALITY FIGURES AND TABLES

APPENDIX D CD OF REPORT WITH HISTORICAL MONITORING TABLES

1.0 INTRODUCTION

This report presents the ground-water and surface-water monitoring results for Trapper Mine for 2020. Mining activities during 2020 include continued expansion of the L pit and initial removal of material above the coal seams in the western portion of the N Pit and in the I Pit West. All other pits were not mined during 2020. Pit dewatering was conducted in the L pit in 2020. Well dewatering was used in 2020 in the G pit area and the F/N pit area in October of 2020 and these volumes of water and pit dewatering volumes are presented in Table 1-1.

Ground-water monitoring of the aquifers associated with Trapper Mine started in 1974 and well data for the monitoring wells is presented in Table 1-2. The ground-water flow regime has been divided into the major sandstones and coal/adjacent sandstone aquifers. This division of the aquifer systems was selected at clay and shale units, which have the potential to retard vertical movement. Figure 1-1 presents the schematic of the aquifer units at Trapper and is useful with the basic well data table in Table 1-2. The 1st White Sandstone and the F coal seam were added to the top of Figure 1-1. The monitoring data tabulations presented in Appendices A, B and C give only the last ten years of data. Appendix D is a CD of this report with all of the historical monitoring data in its Appendices A, B and C. Aquifer properties are presented in Table 2-1 of the 1990 Annual Hydrologic Report.

The Twenty Mile Sandstone is the first major sandstone below the mined coal seam at Trapper Mine. The U coal seam and adjacent sandstones is a minor aquifer between the mined coal seams and the Twenty Mile Sandstone. The Q and R coal seams and sandstone between these two coal seams have been labeled the QR aquifer. This is one of the major aquifers of interest because C, D, E, F, G, K, L and Z pits have mined the Q and/or R coal seams, currently the L pit mines the Q and R seams. The K, L, and M coal seams and the sandstones, which are stratigraphically in this

interval, are called the KLM aquifer. In 2020, the L pit mined the H, H1, H2, I1, I2, I3, K, MK, LK, ML, M, MM, LM, Q, UQ, MQ, LQ and R seams. The KLM aquifer is above the QR aquifer, but below the HI aquifer. The H and I coal seams and sandstone between these two coals have been termed the HI aquifer and have been mined in the past in the A, B, F, G, K, L and Z pits, currently the L pit mines the H and I coal seams. The D pit previously mined the Q and R seams and the I and I1 seams. H pit mined the G seam. The 3rd White Sandstone (G coal and sandstone below) and 2nd White Sandstone (F coal and sandstone below) are monitored at five locations. The I pit will mine the F coal and only overburden stripping was done in late 2020. The Lewis Shale was monitored at one location but well P3 was abandoned in 2016. The Coyote, Deacon, Johnson and Pyeatt Gulch alluvial aquifers are monitored at one site in each of these drainages while the Flume Gulch alluvium is monitored at two locations. The 2019 hydrologic monitoring report, Hydro-Engineering, LLC (2020), presents the discussion of the monitoring results through 2019. Table 1-2 provides basic well data for all wells monitored in 2020. Wells 81-03A, GE-1, GE-2, GE-3, GLUX-1 and GP-6 were not required to be monitored after the first half of 2006. Monitoring of wells GLEV-1, GLEV-2 and GLEV-3 which are located on the east side of the Trapper mine were started in 2015. Wells CY-1, CY-2, CY-3 and CY-A were drilled in 2020 and used with the re-starting of monitoring of well 81-03A to monitor the I and J pit areas.

Springs at Trapper Mine were monitored during 2020 in accordance with the approved monitoring plan. Springs with measured flows of greater than 5 gpm were sampled for full suite water quality parameters. Results of the 2020 spring monitoring are presented in Table B-2 in Appendix B.

Table 1-1 (page 1-5) presents the pit and well dewatering data and volume of water used for dust suppression for Trapper Mine for 2020. This data shows that water was pumped from the L

Trapper Mine pit during 2020. Well dewatering was started in September of 2002 in the G pit and continued in the G/L pit in 2020. The average well pumping rate for 2020 was 18.6 gpm for the G/L pit well dewatering. Well dewatering also occurred in October of 2020 in the F/N pit area at an average rate of 20.7 gpm. This data is useful in interpreting water-level changes and consumptive use.

Surface-water flow and quality were monitored at Flume Gulch (S-1), Johnson, No Name, Ute, Middle Pyeatt, East Pyeatt, Oak, Horse, West Flume, Middle Flume, East Middle Flume, Deal Gulch, East Flume, West Horse Gulch, Deacon Gulch, Deal Gulch #2 and Jeffway Gulch drainages during 2020. The Johnson, No Name, Ute, Middle Pyeatt, East Pyeatt, Oak, Horse, West Flume, Middle Flume, East Middle Flume, Deal Gulch, East Flume, West Horse Gulch, Deacon Gulch, Deal Gulch #2 and Jeffway Gulch drainages are Trapper's NPDES discharge sites 001, 002, 008, 009, 011, 017, 018, 019, 020, 021, 022, 023, 024, 025, 026 and 027, respectively. Sites that had flowing water and were sampled during 2020 are Johnson, No Name, East Pyeatt and Middle Flume.

Some of the data could allow alternative interpretations and some of those interpretations may indicate hydrologic impacts that are significantly different from those presented in this report.

1.1 GROUND-WATER SETTING FOR PERMIT EXTENSION AREA

The geologic setting is the same for the permit extension area as that presented in the Trapper Permit. Three ground-water monitoring wells were added to the 2015 monitoring in the northeast corner of the permit addition area. These wells were completed in the R coal seam, alluvium and H coal seam in the permit extension area. Structure of the coal seams has been extended to cover the permit extension area. These structure maps show that the typical dip to

the north in the northeastern portion of the Trapper permit area is changing to the northwest in Section 28 T6N R90W. The water-level elevations were extended in the permit extension area accounting for the change in the dip of these beds from the north to the northwest.

1.2 GROUND-WATER SETTING FOR THE I AND J HWM AREA

The geologic setting for the high wall mining (HWM) in the I and J pit areas is the same as that was presented for the western portion of the Trapper Permit. Four new ground-water monitoring wells were added to the 2020 monitoring in the northwest corner of the permit area. These wells (CY-3, CY-2, CY-1 and CY-A) were completed in the 3rd White Sandstone, 2nd White Sandstone, 1st White Sandstone and Coyote alluvial aquifers in the northwest portion of the permit area. Monitoring of the 3rd White Sandstone well 81-03A was also re-initiated in 2020 for this area. The structure maps show that the typical dip is to the north in this portion of the Trapper permit area. The 2020 water-level elevations for the 3rd White Sandstone were adjusted for the additional data in this area of the permit. The heads in the new monitoring wells show that this area of the Trapper permit is a discharge area with heads in the 3rd and 2nd White Sandstones being larger than the heads in the 1st White Sandstone and alluvium causing groundwater to move upward.

TABLE 1-2. BASIC WELL DATA FOR THE TRAPPER MINE WELLS

WELL NAME	NORTH. COORD.	EAST. COORD.	AQUIFER	TOTAL DEPTH (ft-mp)	WATER LEVEL				MP ELEV. (ft-msl)	STICKUP (ft)	PERFORATED INTERVAL (ft)
					DATE		DEPTH (ft-mp)	ELEV. (ft-msl)			
P-5	413756	1426170	2ND WHITE	20.9	11/19/2020	>	20.90	< 6430.20	6451.10	1.1	0 - 21
P-8	412134	1426755	3RD WHITE	33.2	11/19/2020		13.99	6481.01	6495.00	2.2	0 - 35

NOTE: MP = measuring point, MSL = mean sea level, LSD = land surface datum
A "-" (minus sign) in water level equals height above MP signifying a flowing well
* = wells destroyed by mining
# = wells in bond release

2.0 GROUND-WATER LEVELS

Water level or water pressure has been measured in 31 wells at Trapper Mine in 2020. Wells 81-03A, CY-2, CY-3, GD-2, GF-4, GP-3 and GP-4 were flowing wells in 2020 and pressure readings on these wells have been converted to static water head in feet above the measuring point. The water levels are prefixed by a negative sign to indicate a water level above the land surface. Wells GA-1 and GA-2 were destroyed by mining in 1996 (see Hydro-Engineering, L.L.C., 1997 for where these two wells were located) and well GP-1 was destroyed by mining in 2003 (see Hydro-Engineering, LLC 2003). Monitoring of wells GB-1, GB-2, GB-5, GF-1, GF-2 and GF-3 ceased at the end of 2003. Wells 81-03A, GE-1, GE-2, GE-3, GLUX-1 and GP-6 ceased monitoring in mid-2006 after their removal from monitoring. Monitoring resumed at well 81-03A in 2020.

The locations of the monitoring wells are shown on enclosed Maps No. 2-1 through 2-3. Well GD-1(2) is completed in the Twenty Mile Sandstone. Four wells, GD-2, GF-6, GLEV-1 and GP-5 are used to monitor the QR aquifer. Wells GD-3 and GF-11 are completed in backfill derived from the QR aquifer and, therefore, are also used to monitor the QR aquifer. Wells GP-2, GP-4, and GP-8 are used to monitor the KLM aquifer. Six wells, GC-1, GF-4, GLEV-3, GP-3, GP-7, and GMP-1 are used to observe changes in the HI aquifer. Wells GF-5 and GF-7 are completed in backfill material derived from the HI aquifer and are also used to monitor the HI aquifer. Wells CY-3, GC-2, P-8, and GP-9 are used to monitor the 3rd White Sandstone aquifer. Well CY-2 and P-5 are completed in the 2nd White Sandstone between the G and F coals. Well CY-1 is completed in the 1st White Sandstone. Well P-3 was perforated in the Lewis Shale and monitoring of this well ceased in late 2016. Six alluvial wells, COY, GC-3, CY-A, GLEV-2, P-1 and J-1, are used to monitor the Flume, Coyote, Deacon, Pyeatt, and Johnson alluviums with two of these wells completed in the Flume alluvium.

2.1 GROUND WATER-LEVEL CHANGES

2.1.1 SUMMARY

Significant mine activities during 2020 included the continued expansion of the L pit. Mining in the F pit, which started in 1997, ceased mining in 2011 with only reclamation activities in 2012 through 2020 in this area. Mining was initiated in 2001 in the G pit, which was idle in 2010 through 2020. The K pit was mined in the K, MK, LK, ML, LL, M, Q and R seams in 2015 with only reclamation activities in 2020. L pit mined in seams H, H1, H2, I1, I2, I3, K, MK, LK, ML, M, MM, LM, Q, UQ, MQ, LQ and R in 2020. Dewatering occurred in only the L pit during 2020 with a volume of 12.73 ac-ft pumped. Well dewatering of 32.79 ac-ft was produced in 2020 near the G/L and F/N pits.

Annual precipitation for 2020 was below normal at 13.47 inches, compared to the Trapper record and long-term record (Figure 2-1 and Table 2-1). The 2013 through 2015, 2017 and 2019 precipitations were at or above normal while the 2016, 2018 and 2020 precipitation were below normal, relative to the Trapper average since 1978 (see Figure 2-1). Two of the last four years were above normal while the 2018 and 2020 were below normal. Recharge in this geographic setting is directly related to precipitation.

The effects of natural recharge variations on the respective aquifers can be observed in wells located in undisturbed areas away from the influence of mining activities. Wells GC-2, GC-3 and GP-9 are used to indicate natural response in the past but need to be used with caution starting in 2000 due to mining moving into this area. Well GC-3 exhibited the alluvial water-level response with an overall gradual decline in water levels in 2019 and 2020 after the rise in November 2018 and February 2019. The effects on the 3rd White Sandstone aquifer are observed in wells GC-2 and GP-

9. Wells GC-2 and GP-9 show an overall steady water levels in 2019 and 2020 showing minimum affects from the below average precipitation in 2018 and 2020 and the above average precipitation in 2017 and 2019. The HI aquifer (GP-7) is characterized by a very gradual decline the previous seven years with this well going dry in mid-2018 and continuing through 2020. The KLM aquifer in well GP-8 showed a decline in 2001 through 2005 with a water level rise in 2006 and fairly steady levels in 2007 through 2014. A gradual water level decline was observed in 2015 through the first half of 2020 in well GP-8 with a larger decline in the last two water levels. A significant amount of well dewatering occurred from the G pit area in 2020.

Steady water levels had been observed the last nineteen years in well GMP-1 except for a small increase during 2005 through 2011. The previous ten years show a water level rise due to the movement of Pit A to the east of this area. The decrease in water levels in wells GD-2 and GD-3 in 2006 were caused by deep exploration drilling in this area. Water levels in these two wells gradually rose in 2007 and overall increased a larger amount in 2008. Water levels continued to overall gradually rise into 2011 and then became overall steady in well GD-2 but declined in well GD-3 until a rise was observed in 2016. The 2017 through 2020 water levels in these two wells were overall fairly steady. The water levels in KLM well GP-2 overall increased from 2008 through 2011 but steadily declined in 2012 through 2019 and increased in 2020. The previous decline could have been caused by the decrease in recharge and mining in this area but the more recent declines are likely due to less recharge. Water level in well GP-5 is useful in defining natural variations in the QR aquifer for 2020. Water levels in well GP-5 show a rising trend from 1993 through 2002. Water levels in this well then were fairly steady for five years with another overall rise from 2007 through 2011. Water levels in GP-5 were fairly steady in 2012 through 2014 and a small decline in 2015 and 2016 likely due to less recharge but fairly steady in 2017 through 2019 and a small rise in 2020. Water-level changes are discussed in more detail in the following section.

2.1.2 WATER-LEVEL CHANGES

Water-level changes for 2020 are presented in Figures A-1 through A-12 in Appendix A. The table in Appendix A lists data from 2011 through 2020 and the historical data for the Trapper Mine is presented on the attached CD in Appendix D. The wells are grouped on the water-level plots according to aquifer where possible but, in most cases, are grouped by similar water-level elevations. Table A-1 in Appendix A presents a tabulation of the water-level elevations for each of the monitoring wells. Figure 2-1 and Table 2-1 present the total annual precipitation at the Trapper Mine from 1978 through 2020. Precipitation declined from a high in 1983 to a low in 1988 and had increased again to a peak in 1993 with a below average value in 1994. The years 1995 through 1997 had above average precipitation relative to the Trapper Mine record, while 1998 through 2004 were below. The precipitation in 2005 through 2011 was above or near normal while precipitation in 2012 was slightly below the 1988, 1994 and 2002 low precipitation years and 2013 precipitation was equal to the Trapper Mine average while 2014 and 2015 were slightly above, 2016 slightly below normal, 2017 and 2019 above normal and 2018 and 2020 below normal. Water levels in many of the wells reflect the natural variations in recharge. These changes may lag the actual precipitation events due to the time it takes the head change to move through the aquifer to the monitoring well.

Figure A-1 presents water levels versus time for wells GF-5 and P-5. The wells are completed in the HI backfill and 2nd White Sandstone aquifers, respectively. Water levels in well GF-5 slightly rose in 2007 and 2008 and have been fairly steady through 2020. Well P-5 went from being dry in early 2010 to recovering four feet in late 2010 and 2011 but then was dry except for one or two quarters in each of the last eight years and was dry during each quarter in 2020.

The GC wells (GC-1, GC-2, GC-3, see Figure A-2) are located near the northeast corner of the permit area (PA) slightly more than 1100 feet from mining activity. These wells are completed in the HI, 3rd White and alluvial aquifers, respectively. The water-level changes in these

wells may not still be good indicators of natural recharge impacts on these aquifers due to the upgradient mining. Water levels in well GC-1 have been overall steady from 2003 to 2009. In 2010 and 2011 the water level rose while a decline was observed in 2012 through 2020. The fourth quarter water level decline in well GC-1 needs to be confirmed prior to giving this decline any significance. Water levels in well GC-3 show some seasonal effects. Water levels in well GC-2 were overall steady from 1999 to 2005, while overall gradually increasing in 2006 through 2016 and fairly steady 2017 through 2020. Changes in these three wells are probably natural. The alluvial aquifer response indicates continuation of above average recharge in 2011 from higher precipitation for the previous six years, a gradual decline in 2012 and followed by fairly normal seasonal variations through 2020.

Figure A-3 presents the static water-level elevations for wells GD-2, GD-3 and GP-9. These wells are completed in the QR, QR backfill and 3rd White Sandstone aquifers. In 2006, water levels in wells GD-2 and GD-3 declined sharply the first quarter of 2006 and then became fairly steady with a large increase in water level in 2008. Water levels overall gradually rose in 2009 into 2011 in wells GD-2 and GD-3 before declining for four years and gradually rising in 2016 in well GD-3 and overall steady in 2017 through 2020 in these two wells. The earlier large water level declines are thought to be due to drilling for deeper coal in this area. Water levels in 2011 and 2012 are higher than any historical level in this backfill well. Backfill well GD-3 is approximately 1200 feet upgradient of well GD-2. Well GD-3 is located topographically higher in the northern side of the D pit than the GD-2 location. Water-level changes in well GD-3 have been more gradual than changes in well GD-2. The unconfined backfill aquifer's storage parameter would be much larger than the storage coefficient for the confined aquifer at GD-2 and, therefore, would be expected to dampen responses.

Water levels in well GP-9 have been overall steady the last few years. This water-level change is likely natural in this well.

Figure A-4 presents water levels for wells GF-7 and P-8. These wells are completed in the HI backfill and 3rd White Sandstone aquifers, respectively. Water levels in well GF-7 (see Figure A-4) were steady in the last six years. The water levels in well P-8 declined in 2012 and since have been overall steady. The larger storage value in the unconfined backfill aquifer may dampen the effects of dry and wet years. The recovery from the A pit mining in this area may be nearly completed.

Water levels for well GF-4 are presented in Figure A-5. A large rise in water level in well GF-4 was observed in the last half of 1999 after the repair of the casing on September 29, 1999. Water levels overall were fairly similar the last few years in well GF-4. Mining occurred south of well GF-4 in the early 1980's and is expected to limit water-level changes in the HI aquifer near well GF-4. Water levels in the upgradient unconfined backfill aquifer do not fluctuate as much as the confined HI aquifer. The backfill aquifer may prevent the lower recharge years from affecting the water level down gradient in the HI aquifer. It is also possible that the backfill spring in Johnson Gulch may be limiting the head in the backfill aquifer.

Wells GF-6 and GF-11 are completed in the QR aquifer and QR backfill, respectively. Backfill well GF-11 is located on the downgradient side of the inactive E pit, while well GF-6 is located downgradient of the pit. GF-11 is 1150 feet upslope and upgradient of GF-6. Overall increases in water levels were observed in wells GF-6 and GF-11 for 2008 with similar but smaller seasonal changes observed in 2009 and 2010 (see Figure A-6). Large seasonal changes were observed in 2011 with overall higher water levels. Water levels in the backfill well overall declined in 2012 through 2015 with a small overall rise in 2016 and overall steady levels in 2017 through 2020 while the levels were steady down gradient in the QR aquifer until a small decline in 2020.

The head in well GF-11 is nearly 22 feet above the head in well GF-6. The water levels in the backfill aquifer may be near fully recovered from mining.

Figure A-6 also presents the water levels for new wells GLEV-1, GLEV-2 and GLEV-3 which are located in the northeast corner of the permit and these wells are completed in the R coal, alluvium and H coal respectively. Yearly water level changes have been observed in the H coal during the last few years at this location with rises early in the year but overall water levels have been steady. Steady water levels have been observed in the R coal the last six years. Data from well GLEV-2 shows that the alluvium is dry at this location.

Figure A-7 presents water levels for GP-7 and GP-8, which are located very near the eastern boundary of the PA. They are completed in the HI and KLM aquifers and may provide undisturbed baseline data for these intervals but could be influenced by mining for the last few years. Water levels in well GP-7 overall had been steady for several years with a very slight decline in 2017 and going dry in mid-2018 through 2020. A slight increase was observed in 2010 and 2011 in well GP-8 after 3 years of steady water levels from 2007 through 2009. Water levels in well GP-8 gradually declined in 2015 through 2020 after gradually rising in 2014. A larger decline was observed in well GP-8 in the last half of 2020. Both of these water level changes are thought to be showing natural responses but could be influenced by the mining that is greater than 1900 feet away.

Well GP-2 (Figure A-8) is located in a previously undisturbed area near the eastern boundary of the PA. Water levels rose in 2008 through 2011 in well GP-2 to a similar level as existed prior to 1999. A large decline in water levels started in 1999. A smaller decline occurred in 2012 through 2019, which is likely due to less recharge. A small water level rise was observed in 2020.

Wells GP-3 and GP-4 are less than 1000 feet downgradient from A pit. Both are flowing wells completed in the HI and KLM aquifers, respectively. Water levels in these two wells had shown similar responses in water levels due to changes in precipitation but the 2005 through 2011 water level changes were different (see Figures A-9 and A-10). Water levels in well GP-3 have recovered to above pre-mine levels in this area and show that any depletion of water from upgradient mining has been replaced by recharge to the HI aquifer. The overall gradual declines in water levels in well GP-3 in the years just prior to 2005 are probably a function of below normal precipitation during this period. The water level in well GP-4 has also recovered to pre-mine levels but observed variable levels in 2004 through 2020.

Well GMP-1 (Figure A-9) is completed in the HI aquifer to monitor ground-water conditions downgradient of the ash disposal site immediately south in A pit. Water levels became steady in 2001 and stayed fairly steady for the next six years with a small increase in 2006 through 2011. Overall steady water levels were observed in 2012 through 2020.

Figure A-10 also presents water levels for the well COY (alluvium). Water levels at the COY well started to decline in 2009 after seven years of overall rising. Overall this gradual decline has continued through 2016 with a small rise in 2017 and an overall gradual decline in 2018 through 2020 but levels are still higher than they were in the 1990s. The unconfined alluvial aquifer generally responds gradual to recharge changes. The 2008 and 2009 water-level elevations were larger than the natural high water levels in 1985 and 1986.

Well GP-5 is completed in the QR aquifer and located immediately downgradient of A pit. Water-level data from 2011-2020 is tabulated in Table A-1 in Appendix A (see attached CD for all historical water-level data). Figure A-11 presents the water level versus time plot, showing a rising trend for the previous six years during the period of above normal precipitation and fairly steady water levels during the 2012 low precipitation year and a small decline in 2014 through 2016

with the slightly above normal precipitation to slightly below normal precipitation. A very gradual rise was observed in 2017 through 2020. These responses are interpreted to be due to an increase in recharge followed by a decrease in recharge with slightly larger recharge in 2017, slightly less recharge in 2018 and more in 2019 and 2020. These water levels show no response to the higher precipitation in 2005 while a good response is shown to the higher 2006 through 2011 precipitation. This data indicates that a lag of one year in the water level responses in well GP-5 to precipitation may occur. These responses indicate that the mining from the QR seams, which is nearest in the F pit mining that began in 1997, has not significantly affected water levels in well GP-5.

Figure A-11 presents the change in water-level elevation for alluvial well P-1, located in the Pyeatt drainage north of the PA. This data demonstrates classic seasonal responses, highs in winter/spring and lows in late summer/fall. Overall the water levels have been fairly steady in well P1 in 2012 through 2014, declined in 2015 but recovered in 2016 to overall steady levels. Water-level elevations for the Johnson Gulch alluvial well J-1 are also presented in Figure A-11. The J-1 water levels remained steady in 2012 through 2020, indicating that variations in precipitation have not affected the Johnson Gulch alluvial water levels.

Figure A-12 presents the change in water-level elevation for the four new wells in the northwest portion of the Trapper Mine near the HWM in the I and J pits. This limited data shows that the heads in the 3rd and 2nd White Sandstones in wells CY-3 and CY-2 which are slightly above the top of the casing are higher than the heads in the 1st White Sandstone and the Coyote alluvium in wells CY-1 and CY-A. Additional monitoring time is needed to determine if these water levels have a trend.

2.2 GROUND WATER-LEVEL ELEVATION (PIEZOMETRIC MAP SUMMARY)

Hydro-Engineering developed three piezometric maps to show the water level flow patterns for the QR, HI and 3rd White Sandstone aquifers at Trapper Mine. Water levels from the fall of 2020 were used to develop these maps. The structure maps for the coal seams were used to extend the piezometric contours in the permit extension area on the east side of Trapper Mine along with the water-level elevations from the GLEV wells. The change in the dip of the beds from mainly to the north to the northwest in the extension area caused the gradient in the ground water to gradually change from the north to the northwest. The new 3rd White Sandstone well CY-3 in the northwest portion of the Trapper permit area was used with an updated water level for well 81-03A to adjust the water-level elevations in this area.

Map No. 2-1 presents the water-level elevations for the QR aquifer. The water-level elevation is presented for the QR wells: GD-2, GF-6, GLEV-1 and GP-5 and backfill wells GD-3 and GF-11. The ground-water flow in the QR aquifer is mainly to the north. Mining has only affected the QR aquifer close to the D, E, F, G, K, L and Z pits by causing drawdowns very near the pit edges. The installation of backfill wells GD-3 and GF-11 has defined the depressed elevations in the backfill areas. The water levels from these wells were overall steady during 2020. These water level changes are likely due to seasonal recharge in recent years. The backfill water levels will likely stabilize lower than the pre-mine levels due to the increased permeability of the backfill aquifer, which allows the water in the aquifer to be transmitted at a lower gradient. The gradient calculated for the backfill near D pit is less than 0.05 ft/ft, compared to the undisturbed gradient of 0.12 ft/ft. The heads in the northern end of the backfill aquifer will likely recover above the pre-mine level. Backfill springs are not expected to develop near the northern end of the QR backfill because backfill water levels would have to recover greater than a few tens of feet to reach the lower land surface elevations. Table 2-1 of the 1990 Annual Hydrologic Report (Hydro-Engineering,

1991) presents aquifer properties at Trapper Mine. The permeabilities from the backfill aquifers are significantly greater than the coal aquifers that they replace.

The water-level contours extend through the pit areas for the F, G and Z pits because the R seam was not mined in these pits and therefore the QR aquifer still exist under these pit floors. Some drawdown would be expected in these areas of the QR aquifer and are indicated by the contours.

The water-level contours in the northeast corner of the Trapper Mine with the water-level elevation from well GLEV-1 shows that the flow direction in the QR aquifer turns from the north to the northwest due to the change in the dip of the coal seams in this area.

The QR water-level map at Trapper Mine was very similar in 2020 to the 2019 water-level elevations. Gradients and flow directions for the QR aquifer in 2020 are similar to those observed in 2019.

Map No. 2-2 presents the water-level elevation contours for the HI aquifer in the fall of 2020. Wells GC-1, GF-4, GLEV-3, GP-3, GP-7, and GMP-1, which are completed in the HI aquifer, and backfill wells GF-5 and GF-7, were used in the development of this map. Wells GF-5 and GF-7 are completed in the backfill in the area where the H and I coal seams were mined. Flow direction in the HI aquifer has been changed mainly near the A pit near well GF-4. The overall flow regime in this aquifer is northerly, similar to that observed in 2019 (see Hydro-Engineering, 2020). Flow direction in the HI aquifer in the permit extension area on the east side of the Trapper Mine changes to the northwest due to changes in the structure of the H and I coal seams. The addition of the GLEV-3 water-level elevation shows that the ground-water flow direction in the HI aquifer changes to the northwest in the northeast corner of the Trapper permit area.

The ground-water gradient between the backfill aquifer and the un-mined HI aquifer downgradient is relatively flat as it is in the QR backfill. The contours in the HI aquifer have also

been changed on the east side where previous mining in the A pit has likely caused water level declines near this pit. The D and K pits were used to mine the I seam and the K pit also mined the H and I seams in 2010 through 2012 and the I2 seam in 2013. The H and I seams were mined in the K pit in 2014 while the L pit mined the I seam in 2014 and the H and I seams in 2015 through 2020.

The 3rd White Sandstone aquifer water-level elevations are presented on Map No. 2-3. Wells GC-2, P-8 and GP-9 were used in the development of this map. Flow direction in the 3rd White Sandstone is mainly toward the north, as expected. The 2020 contours are very similar to those observed from the last few years except for the extension to the east of the depression in the piezometric surface in the 3rd White Sandstone defined by the water-level elevation in well CY-3. This depression in the piezometric surface indicates this is a discharge area for the 3rd White Sandstone aquifer.

The flow direction in the 3rd White Sandstone changes to the northwest in the permit extension area on the east side of the Trapper Mine. Water-level elevation contours have to shift to the northeast in the extension area because the base of the 3rd White Sandstone would be above the water-level elevation if they continue to the east. The saturated thickness in the 3rd White Sandstone in the northeast portion of the extension is thought to be only a few tens of feet with this sandstone being dry farther south in the permit extension area.

3.0 GROUND-WATER QUALITY

Appendix B presents the ground-water quality data for the Trapper Mine. This appendix tabulates 2011-2020 data in Table B-1 and presents TDS and sulfate plots versus time to convey changes in the major constituent water quality (see attached CD in Appendix D for all historical data).

Appendix B also presents the 2011-2020 spring and seep water-quality data (see attached CD in Appendix D for all historical data). Water quality for the springs and seeps are included in this section because their source is ground water. Section 3.6 presents a discussion of the spring and seep water-quality data.

3.1 TOTAL DISSOLVED SOLIDS (TDS)

Figures B-1 through B-7 present plots of the TDS concentrations for the Trapper Mine wells. The wells have been grouped together based on aquifers.

Figure B-1 presents the TDS concentrations versus time for two QR aquifer wells GD-2 and GD-3. Well GD-3 is a backfill well in the QR aquifer. TDS concentrations had been fairly steady the previous eleven years in well GD-3 but have increased in 2010 and 2011 then declined in 2012 and very gradually increased in 2013 through 2020. The fluctuation in this backfill aquifer is well within natural ranges and may be very similar to variations that would have occurred in the QR aquifer at this location. Some of the TDS in the backfill aquifer may be due to leaching from the backfill material. The TDS in this backfill aquifer is greater than it is downgradient in the R Coal at GD-2 which overall increased in concentrations in 2008 through 2020. This is likely the movement of higher concentration from the GD-3 area to well GD-2.

Figure B-2 also presents a group of four QR wells. Well GF-11 is an equivalent QR aquifer well in the backfill. The 2020 TDS concentrations are similar values observed the last fourteen years in backfill well GF-11 with a very gradual increasing trend and below its peak in 2001 and 2002. Concentrations in the QR aquifer are monitored downgradient at well GF-6 and have shown no influence from the upgradient mining, except for a very slight overall increasing trend. These small changes are well within natural variations. Figure B-2 also presents the TDS concentrations for QR wells GP-5 and GLEV-1. TDS concentrations in well GP-5 have been similar with time with a very gradual increasing trend while a slightly smaller concentration were observed in well GLEV-1 with a very gradual increasing trend.

Figure B-3 presents the TDS concentrations for three KLM aquifer wells. The data for well GP-4 is presented in red square on Figure B-3 with steady values prior to an overall very gradual decrease in concentration during the last few years. TDS concentrations for two of the eastern KLM wells, GP-2 and GP-8, are also shown on this figure with concentrations generally between 700 and 800 mg/l. Variable TDS concentrations that are overall steady have been observed in these two wells for the last several years with a very small increasing trend the last few years.

Figures B-4 presents the TDS concentrations versus time for the HI aquifer wells. The TDS in HI aquifer well GF-4 had gradually increased in concentrations with time but has been fairly steady for the last several years. The small changes are well within natural fluctuations in this well but could be due to upgradient mining. TDS concentration in backfill well GF-5 is slightly greater but is still well within the natural range for the HI aquifer. Significantly higher TDS values have been observed in backfill well GF-7 with the concentrations in the last twenty-three years being between the lower levels prior to this period and the maximum historical values from this well. TDS

values in this backfill aquifer will likely fluctuate until they decline to a value similar to the HI aquifer in this area. A very gradual declining trend seems to be occurring the last few years.

Wells GMP-1 and GP-3 are two HI aquifer wells north of the A pit and their TDS data are shown on Figure B-5. Higher values of TDS were observed in well GMP-1 during 2006 through 2020 with an overall increasing trend. This well is immediately downgradient of the reclaimed A pit and is likely showing fluctuations from the backfill aquifer. The previous TDS values and fluctuations in well GMP-1 are similar to those in well GC-1. The TDS in well GC-1 had to be natural until mining reached this area the last few years. The recent higher TDS values in well GMP-1 are likely caused by the upgradient mining. A gradual rise in the backfill water level in this area occurred through 2011 but has recently been fairly steady. The overall TDS concentrations in well GC-1 in 2020 are similar to values that existed prior to mining in this area. The 2006 through 2009 monitoring indicates the 2005 increases were not representative of large portions of the aquifer in this area. TDS concentrations in HI aquifer well GP-3, further downgradient of well GMP-1, have overall been steady for the period of observation. TDS concentrations in eastern well GLEV-3 have varied, showing that TDS varies naturally over a large range in this aquifer. Fluctuations observed in wells GC-1, GLEV-3 and GP-7 except for the last few years must be natural due to their location. The TDS in the new HI aquifer well in the northeast corner of the Trapper permit area has a higher concentration than other HI wells in this area. The flow in the HI aquifer to well GLEV-3 would be from the southeast to the northwest and therefore concentrations in well GLEV-3 should be natural.

Figure B-6 presents the TDS for 3rd White Sandstone wells 81-03A, CY-3, GC-2, GP-9 and P-8. Concentrations in each of these wells have been fairly steady for the last few years. The TDS for the first fourteen years for well P-8 shows fairly steady concentrations prior to a large increase in

1995 over three years to a value of approximately 4000 mg/l. The 2020 TDS concentrations in well P-8 were steady but indicating a small declining trend may have started. The increase in well P-8 is above the levels expected for the 3rd White Sandstone and is likely due to the upgradient mining based on the timing and magnitude of the increase. However, some of this higher level could be natural based on natural large historical concentrations observed in 2nd White Sandstone well, P-5. Concentrations are expected to decline in the future if the increase is due to upgradient mining. The TDS values for 2nd White Sandstone well P-5 have varied from 2500 to 3000 mg/l range prior to mining in this area. Natural water-quality concentrations in the 1st, 2nd and 3rd White Sandstones are expected to vary over a similar range. The 2020 TDS in well 81-03A is very similar to the historical values measured in this well while the TDS in well CY-3 is smaller.

Figure B-7 presents the TDS concentrations versus time for alluvial wells CY-A, GC-3, P-1, J-1 and COY. TDS concentrations in Pyeatt alluvial well P-1 were variable in 2020 and similar but slightly higher than historical levels. The TDS concentrations in alluvial ground water in Johnson Gulch (J-1) had been fairly steady since 2000 but had very gradually increased the last seven years prior to steady values in 2020. The recent Johnson Gulch alluvial ground water is within the natural range for TDS in this aquifer. These TDS values and variations are very similar but slightly higher than natural values observed in Flume Gulch alluvial well, COY. The TDS measured in the Coyote alluvial well CY-A is similar to the TDS in the COY well.

Flume Gulch has two alluvial monitoring wells, GC-3 and COY. TDS concentrations overall have been steady in well GC-3 with variations observed the last few years similar to previous values. The 2020 TDS concentrations in the COY well were similar to higher natural values in this well. The TDS concentrations in the COY well and historical variations in well P-1 show that recent Johnson alluvial TDS concentrations are slightly higher than natural alluvial concentrations in the

alluvial aquifers in this area. The natural variability in surficial alluvial aquifers in this area is large and the upper limit may have not been fully defined by historical measurements.

3.2 SULFATE

Figure B-8 presents the sulfate concentrations for QR wells GD-2 and GD-3. Sulfate in backfill well GD-3 were steady between 2000 and 2009 and then overall increased until 2011 with fairly steady values through 2016. The 2017 through 2020 values indicate a very gradually increasing trend. This indicates that the sulfate fluctuations in the backfill aquifer may be larger than the native QR aquifer. Future monitoring of this well will define whether sulfate concentrations will increase in the backfill aquifer when water levels rise to a higher level in the backfill material. Concentrations in well GD-2 had overall gradually increased for several years but declined in 2006 and 2007 prior to an overall larger increase in 2008 through 2020. The recent sulfate concentrations in well GD-2 indicate the QR aquifer near well GD-2 are affected by the upgradient backfill aquifer water quality.

Figure B-9 also presents sulfate concentrations for additional QR wells. This figure shows that sulfate concentrations in backfill well GF-11, which is upgradient of QR well GF-6, were decreasing in 2006 and 2007, overall steady in 2008 through 2017 and a very gradual increasing trend in 2018 through 2020 with all of these concentrations lower than the historic peak in 2001. Future monitoring is needed to define the maximum sulfate concentration in this backfill aquifer which may have been defined in 2001 and 2002. The sulfate concentrations gradually increased in well GF-6, downgradient of well GF-11 with a very gradual increasing trend the last eight years. Sulfate concentrations for the last several years has also overall very gradually increased in QR well GP-5. The sulfate in well GLEV-1 is very small and steady in 2020.

Figure B-10 presents the sulfate concentrations for KLM aquifer wells GP-2, GP-4 and GP-8. Sulfate concentrations in eastern well GP-2 have varied significantly but were similar in 2012 through 2020 to historic values. These changes are within the natural historic range defined at this well prior to mining in this area. Overall steady sulfate concentrations in well GP-4 have existed the last few years with some years at lower levels and others at higher concentrations but all within historical range for sulfate from this well. Sulfate concentrations in well GP-8 have stayed steady and small as mining approaches this area.

Sulfate concentrations for the HI aquifer wells are presented in Figures B-11 and B-12. The sulfate concentrations in the HI aquifer wells in Figure B-11 are fairly similar except for the values in backfill well GF-7, which are substantially greater than those in downgradient well GF-4. Steady to very gradual decrease in sulfate concentrations have been observed in well GF-4 after a very gradual increase for several years. These small variations are well within the natural variation of sulfate concentrations in the HI aquifer but could be defining the very small effects of the backfill aquifer upgradient. Sulfate concentrations in backfill well GF-7 overall gradually declined in 2010 through 2014 and overall steady in 2015 through 2020 with smaller values in 2018 and 2019. The water levels for the last few years have been fairly similar in well GF-7, indicating that these changes are not due to new backfill being saturated but likely due to variations in recharge. Sulfate concentrations have stayed low and steady in backfill well GF-5 in 2020. These small changes may be defining the very small effects of upgradient mining but the changes are well within natural ranges. This monitoring indicates that if the HI aquifer has been affected in wells GF-4 and GF-5 by upgradient mining, it has been very small.

Sulfate concentrations in well GMP-1, which are shown on Figure B-12, have been highly variable indicating an increasing trend during 2006 and 2007 and an overall similar increasing trend

in 2008 through 2017. The 2020 data is very similar to the 2017 and 2018 values and indicates steady concentrations except for the two lower values in 2019. The water level in well GMP-1 had been steadily increasing for several years prior to becoming fairly steady in 2002 and then gradually increasing for several years prior to being steady the last eight years. Sulfate concentrations may stay higher and variable in this well for several years. Sulfate concentrations in this well are influenced by the sulfate concentrations in the backfill aquifer upgradient of GMP-1. The sulfate concentrations in well GP-3 had shown a gradual increasing trend but concentrations had been steady the last sixteen years until the slightly smaller concentrations in 2018 through 2020. Sulfate concentrations in eastern HI aquifer well GC-1 have been similar to the previous higher values in well GMP-1 and had to be natural until the last few years. The sulfate concentration in well GLEV-3 are similar to those in well GMP-1 but have to be natural due to the ground-water flow direction at this well. Therefore, an upper limit for sulfate concentration that is greater than 600 mg/l may be needed to indicate that the increases may be due to the mining operation. The 2020 value from well GC-1 was similar to past values but significantly less than the value to the east from well GLEV-3.

Figure B-13 presents the sulfate concentrations for three 3rd White Sandstone wells. The sulfate values from well P-8 have overall very gradually decreased the last six years while they have been elevated for more than twenty years. The magnitude and timing of the prior increase in sulfate concentrations in well P-8 indicate that this is due to mining. The sulfate changes in wells 81-03A, CY-3, GC-2 and GP-9 are within the natural range of concentrations for this aquifer.

Figure B-14 presents the sulfate concentrations for alluvial wells CY-A, GC-3, P-1, J-1 and COY. The sulfate concentrations in alluvial well P-1 have been variable with recent values slightly higher than historical natural values for this well. The sulfate concentrations for Johnson Gulch well, J-1, gradually increased the last few years with these recent values being slightly higher than

the natural levels in the Flume Gulch alluvium at well COY. The sulfate value for the Coyote alluvial well CY-A is similar to the alluvial J-1 and P-1 concentrations. Sulfate concentrations in the Flume Gulch wells (GC-3 and COY) have fluctuated from approximately 300 to 1200 mg/l. The natural variability in sulfate concentrations for the surficial alluvial aquifers in this area would be expected to be large and the full range of historical natural values may have not been defined.

3.3 pH

Field pH is an important parameter to monitor because some coal spoils have the potential to increase acidity of the ground water, which increases the mobility of most of the heavy metals. A pH of less than 5 would generally be needed to greatly increase the mobility of heavy metals.

Available pH data is tabulated in Table B-1 of Appendix B. The field pH values for the new CY wells are all above neutral with the field pH above 8 for 3rd White Sandstone wells CY-3 and 81-03A. The field pH of water from the GC wells has generally been slightly above 7.0 and has been at similar values since the initiation of disturbance in this area.

Field pH from well GD-2 slightly decreased in 2005 and near neutral the last fifteen years. The upgradient mining in the QR seams has not significantly affected the pH in this area of the aquifer. The pH values from backfill well GD-3 are near or above 6.7 for 2020, which is near the values in the native aquifer at well GD-2.

Similar pH values were observed for the HI aquifer at well GF-4 in 2020 to those observed in previous years. Backfill well GF-5 had field pH values above 7.0 in 2020, while the field pH for backfill well GF-7 was near neutral. The field pH values in backfill well GF-11 for 2020 were also near neutral and similar to previous years. The field pH in well GF-6 (QR) was also above neutral in 2020.

Well GP-2 (KLM) water was slightly above neutral in 2020. The field pH values for well GP-3 were higher than neutral from the HI aquifer and from well GP-4 above neutral for the KLM aquifer.

Well GP-5 is completed in the QR aquifer and its field pH values are generally above 8. The field pH for well GP-8 (KLM) water had field pH values near 8.0 in 2020. The 3rd White Sandstone aquifer well GP-9 field pH values are typically near neutral.

The alluvial (P-1) and 3rd White Sandstone (P-8) wells in Pyeatt Gulch all contain water with field pH that is generally near neutral. The field pH values for wells GLEV-3 and GMP-1 were near neutral in 2020 while the pH was near 9 in well GLEV-1. The 2020 monitoring did not detect any indication of development of acidic water in the Trapper Mine ground water.

3.4 NH_3 AND NO_3

Concentrations of ammonia and nitrate are presented in Appendix B, starting on page B-56. In general, concentrations of ammonia vary significantly from year to year. Wells 81-03A, CY-1, CY-2, GD-2, GF-5, GF-6, GF-7, GP-2, GP-5, GP-9 and P-8 all contained NH_3 concentrations that are greater than 1.0 mg/l in 2020. Several of these wells are located away from mining and contain natural levels of NH_3 concentrations. All of the NH_3 concentrations observed in 2020 are within the natural range of this constituent at Trapper Mine.

All of the 2020 NO_3 values were below the drinking water standard of 10 mg/l. Well P-5 has historically contained nitrate concentrations above 10 mg/l and this well was dry during the 2020 sampling events.

3.5 OTHER CONSTITUENTS

The major constituents other than bicarbonate and carbonate are presented on pages B-32 through B-43. Declines in sodium concentrations at well GF-7 occurred from 1989 to 1996 with slightly higher values in recent years. Sodium concentrations are much smaller in backfill well GF-11. The SAR values observed in 2020 in water in the Trapper wells were very similar to recently observed and natural values at Trapper Mine. None of the 2020 SAR values indicate a significant trend in this parameter.

The heavy metals with a "t" subscript by their symbol represent total measurements, while the others are dissolved concentrations. The “tr” subscript for iron indicates total recoverable iron. Dissolved and total concentrations are similar for most of the heavy metals, except for iron concentrations in some wells where the total values are significantly greater.

Iron concentrations have varied over large ranges near the mine pits and at distant wells but no consistent trends have been observed. Levels of aluminum, barium, boron, phosphate and manganese have also varied over significant ranges but no consistent trends have been observed. Arsenic, cadmium, chromium, copper and lead concentrations have been low with a few exceptions. Molybdenum, nickel and selenium concentrations have stayed low. The recent radium 226 values have been low and the 2017 through 2020 values for well GF-6 shows that the 2016 value of 5.5 pCi/l was an outlier. The variability of laboratory analysis is greater for this parameter and the 2016 elevated value should not be given any significance.

3.6 SPRING AND SEEP WATER QUALITY

Table B-2 in Appendix B on pages B-68 through B-74 presents the 2011-2020 water-quality data for the springs and seeps at the Trapper Mine. The locations of the springs and seeps that were monitored in 2020 are shown on Maps 2-1, 2-2 and 2-3. Flow from the springs and seeps are shown

on Table B-2, which shows that only the East Pyeatt spring exceeded 5 gpm in its discharge rate in 2020. Water quality from the springs and seeps are similar to the ground-water quality for the site. An increase in TDS concentrations was observed in the East Pyeatt Spring in 2000 with fairly similar values in 2020. The TDS for Coyote spring for 2020 was similar to values measured historically for this site.

4.0 SURFACE WATER

Trapper Mine monitored one stream site and sixteen active NPDES discharge sites during 2020. The stream site Flume Gulch (S-1) was sampled during June 2020 to characterize spring flow at this location. Flow was observed at NPDES sites 001, 002, 011 and 020 in 2020. Sites 001, 002 and 011 had flow each month while site 020 had flow only in April during 2020. Baseline stream site East Pyeatt (S3) is also NPDES site 011. Sites were monitored monthly throughout the year. Sites NPDES 008, 009, 017, 018, 019, 021, 022, 023, 024, 025, 026 and 027 did not discharge during 2020. Maps No. 2-1 through 2-3 show the locations of these surface-water sites.

4.1 SURFACE-WATER FLOW

The 2011-2020 flow data tabulated in Appendix C in Table C-1 represents instantaneous measurements associated with NPDES water-quality sampling (see the attached CD in Appendix D for all historical surface-water data). Recorded surface runoff for NPDES 001, 002, 011 and 020 were similar in 2020 to the 2019 flows at the Trapper Mine except for higher spring runoff in April in 2019 due to the higher precipitation in 2019. The one flow in NPDES 020 was much smaller than the 2019 flow at this site.

Figures C-1 through C-3 present the instantaneous flows versus time for the Trapper NPDES sites for 2020. There was flow during each of the monthly samples of 2020 at NPDES 001 and 002 sites with high flow during sampling of 110 and 348 gpm for NPDES 001 and 002 respectively in 2020. Surface flow at NPDES 011 was observed during each monthly sample with a peak of 132 gpm during four of the monthly samples (see Figure C-2). NPDES 020 had a very small flow during the monthly measurement in April of 13 gpm (see Figure C-3).

5.0 SURFACE-WATER QUALITY

Samples were collected from active sites 001, 002, 011, 020 and S-1 during 2020. Analytical results for these surface water samples are presented in Table C-1 (page C-24). The more frequently measured parameters are presented with the first series of values. The less frequent measured parameters are in two separate groups and shown after the first group of parameters in Table C-1. NPDES sites 008, 009, 017, 018, 019, 021, 022, 023, 024, 025, 026 and 027 had no discharge during 2020 and, therefore, no 2020 water quality data is presented.

5.1 TSS

Figures C-4, C-6, C-8, C-10 and C-12 present plots of total suspended solids (TSS) versus time for the sites 001, 002, 011, 020 and S-1. The 2020 TSS values were small and similar to the low range of previously observed values. S-1 TSS value was very small in 2020. Plots of flow versus TSS for the same sites are presented in Figures C-5, C-7, C-9, C-11 and C-13. As expected, a general increase in TSS for an increase in flow is seen in these plots for the historical data from these sites with the 2020 data supporting the historical relationship between flow and TSS.

5.2 CONDUCTIVITY

The conductivity versus time plot for site NPDES 001 shows a similar, but slightly higher, range of conductivity in 1998 through 2020 to the range observed over the previous few years (Figure C-14). The observed 2020 conductivity data plots within the historical range in conductivity for Johnson Gulch (001) for the low flow rates (Figure C-15).

Figure C-16 presents conductivity concentrations versus time for NPDES site 002. The upper range in conductivity in 2011 through 2020 was slightly less than the upper range for the

previous few years. The range in the 2020 conductivity data was similar to the historical range for low flow and the one higher flow rate. Figure C-17 shows a good inverse relationship between flow and conductivity for the data at this site.

The conductivity values for NPDES site 011 are shown Figure C-18, with values from NPDES site 011 covering most of the historical range in 2020. Figure C-19 shows the 2020 conductivity values from site 011 exist in the upper two thirds of the previously observed conductivities. Figures C-20 and C-21 present the limited data that has been collected at the NPDES 020 site.

Conductivity of water for site S-1 has been fairly steady with time (Figure C-22). The 2020 conductivity is within the range that has been defined at this site. Figure C-23 presents the conductivity versus flow for the S-1 site. The conductivity measured in 2020 for the S-1 site is in the middle of the range measured for this site.

TDS, conductivity and major constituents tend to increase as the ground-water contribution becomes a larger portion of the flow. The values, in general, are within natural ranges but some increase over baseline has likely occurred at NPDES site 001. No long-term trends are indicated by the major constituents except for NPDES site 001, which may have stabilized after several years of generally increasing.

5.3 OTHER CONSTITUENTS

Field pH values for all sites were very similar in 2020 to previous data. Values typically ranged from near neutral to less than 9 for pH values at the surface water sites. Other constituents analyzed showed little change with all minor constituents within their natural ranges. All values addressed in this report above permitted discharge levels have been addressed in the quarterly

NPDES discharge reports (DMR's) and justifications for those values, i.e. storm water, snow cover melt-out, etc., have been submitted to the proper regulatory authorities. No oil and grease was observed during the surface water sampling in 2020.

6.0 OBSERVED IMPACTS ON THE HYDROLOGIC SYSTEMS OF THE TRAPPER MINE

6.1 GROUND WATER

Water-level changes in the last few years for the QR aquifer have been fairly steady mainly due to near normal precipitation for the last few years. Water-level changes were observed in QR aquifer wells GD-2, GF-6 and GLEV-1, along with associated backfill wells GD-3 and GF-11. Water levels in wells GD-2 and GD-3 declined in 2006 and these declines are thought to be due to some deep exploration drilling in this area. Water levels rose in 2008 and 2009, with overall steady water levels in 2011 through 2020 in well GD-2. A gradual decline in water level in GD-3 was observed in 2012 through 2015 with overall steady levels since the decline except for a small increase in 2020. Additional monitoring with time is needed to determine the significance of the decline in wells GD-2 and GD-3 but presently well GD-2 has not completely recovered from the 2006 drop. Wells GD-2 and GF-6 are fairly close to mined areas, overall steady water levels in 2013 through 2020 were observed in wells GD-2 and GF-6. The 2012 responses in well GF-11 indicated that water levels declined due to the decrease in precipitation in 2012 with smaller water level changes in 2013 through 2020 with near normal precipitation. These wells are located near the downgradient toe of D and E pits and/or at the interface of upgradient backfill and the downgradient native QR aquifer. These well locations seem to be relating to changes in precipitation with very little lag in time.

Upgradient mining can cause water-level rises in wells downgradient of the mining by allowing ground water to flow to the downgradient end of the backfilled area quicker. The backfill aquifers are generally more permeable than the native aquifer which also allows ground water to flow faster through the backfill material resulting in more water in the aquifer at this location. The input of additional water to the native aquifer at the north end (toe) of the mine has decreased the

effects mine dewatering has had on water levels in this portion of the aquifer. Water levels in wells GF-6 and GF-11 are thought to be at or above the baseline levels for this reason. The slightly higher water levels in well GD-2 in 1998 than those observed in 1986 after six wet years indicates the post-mine levels under the same conditions may be higher. Springs are not expected to develop at the north end of the D, F and K pits.

The water-level changes for the HI aquifer have generally been influenced less by higher than average recharge in 2005 through 2011, the very low precipitation in 2012, closer to normal in 2013 through 2017, below normal precipitation in 2018 and 2020 and above normal in 2019. The mining upgradient of HI well GF-4, which occurred several years ago, has been long enough in the past to allow water levels to fully recover. The water levels in this HI aquifer well seem to be varying only slightly with changes in recharge rates. Water levels in this well were overall slightly higher in 2007 through 2020 with the near and above normal precipitation except for the low 2012, 2018 and 2020 values. The elevation of the backfill springs likely limits the head buildup in the backfill aquifer, which, in turn, limits the maximum head in the downgradient coal aquifer. Fairly steady water-level responses were observed in the two backfill equivalent HI aquifer wells GF-5 and GF-7. Water levels seem to have reached recovered levels in these two wells. The development of backfill springs may limit the maximum water level in some of these areas of the A pit but the backfill aquifer will maintain less fluctuation in water levels down gradient of the pit.

Water levels in most of the backfill areas are depressed and are not likely to ever recover to pre-mine levels except near the northern end of the mine area. Map 2-1 shows that the levels in the backfill and downgradient aquifers are similar. Well pairs GD-3 & GD-2 and GF-11 & GF-6 present water levels that are very similar in water-level elevation for the backfill and downgradient QR aquifer well. Mining is significantly increasing the permeability of the backfill aquifers which is

a benefit relative to potential yields from the aquifer. The increased permeability will likely not allow water levels to recover to pre-mine levels in the reclaimed pits except near the northern (down-dip) end of the mined area, where levels may be limited by the elevation of backfill springs from the northern pits in this area.

Significant drawdown has developed adjacent to the pits but the extent of these drawdowns is very limited due to the small transmissivity in these aquifers. Recovery of the water levels has occurred over a few years as the pits have moved away from an area. Some water levels will likely not recover to their pre-mine levels due to the different flow characteristics developed with the backfill aquifer and the controlling of the maximum head by backfill springs.

Variations in natural recharge to the 2nd White Sandstone affect this aquifer greatly. Mining effects on the system have not been detected but could be observed in the near future with the I pit HWM.

The TDS of water in backfill wells GD-3 and GF-5 are somewhat higher but similar to those of the native aquifers in these areas. TDS for GF-5 is approximately 1.5 times the pre-mine value but is within natural variability of this aquifer. TDS values for backfill wells GF-7 and GF-11 are much higher than the naturally observed concentrations. TDS in well GF-7 has shown some decline from the peak values in the early 1990's and has been fairly steady for the last nineteen years at a slightly lower level. An overall very gradual decline is being observed the last few years. The TDS values in well GF-11 may have reached its peak in 2001, currently values are much lower than its peak and have been relatively steady from 2006 through 2020 with a very gradual increasing trend. It is likely that the TDS will remain higher for many years before returning to pre-mine concentrations in these two wells. The change in major constituent concentration in water in these two wells will likely decrease during wet cycles and gradually decline as readily soluble constituents

are removed. The water quality in QR well GF-6 has been only slightly affected by the upgradient mining while well GD-2's water quality has been affected more. The remainder of the QR wells are located away from present mining activities and likely not affected.

The water quality in HI aquifer well GP-3, which is close to the reclaimed A pit, has not been influenced by mining. TDS concentrations were steady for the last few years in well GF-4 after a slight increase for several previous years. This small change may be due to mining but is within natural variations for this aquifer. The water quality in HI well GMP-1 likely has been affected by mining. Its concentrations were within the range of natural concentrations until the increase in the last fourteen years. The water quality in HI well GC-1, downgradient of the mining in this area, increased in 2005 but returned to previous level in 2006 through 2020. The water quality in HI well GP-7, which is east of the areas mined, had not been affected prior to going dry in 2018. The TDS from the new HI aquifer well GLEV-3 indicates the natural level in this aquifer can be higher at some locations.

The 3rd White Sandstone wells GC-2 and GP-9 are downgradient of mining starting in 2000 and changes in water quality in these wells in 2020 are similar to previous natural changes. TDS concentrations in 3rd White Sandstone well P-8 were large in 1996 through 2020 and the magnitude and timing of this increase makes it likely that it was caused by upgradient mining in the A pit. Well CY-3 will be used to determine if the I and J pit HWM in the future affects this aquifer.

Significant changes in TDS concentrations have been observed in the alluvial wells GC-3, P-1, J-1, and COY. The changes in the Flume alluvial wells had to be natural prior to 2000, while some of the changes in J-1 water could be due to mining. Overall, the TDS for J-1 were higher than normal from 2000 to 2020 and is slightly higher than the natural levels in the COY alluvial well. The variations in 2020 TDS in Pyeatt alluvial well P-1 are slightly higher than natural levels

observed for the alluvial aquifers and could be slightly affected by mining. The full range of TDS in the alluvial aquifers would be expected to be large in this surficial aquifer and may have not been defined at the Trapper site.

Sulfate concentrations in well GF-4 were fairly steady in 2020 while the sulfate concentrations in well GD-3 overall had been fairly steady but a very gradual increasing trend is being observed in the last few years. Sulfate concentrations in well P-8 overall have been at similar levels in recent years while the 2020 value indicates a decline. Concentrations have overall been steady in well GF-11 for the last several years after declining from a peak but the recent values indicate a very gradual increase. Sulfate concentrations have overall increased during 2006 through 2017 in well GMP-1 with the 2020 and 2018 levels indicating steady concentrations. Sulfate concentrations in well GF-7 were variable but overall gradually declined for the last several years to a level less than its maximum level in the early 1990's. Sulfate in wells GD-3, GF-7, GMP-1, GF-11 and P-8 have likely been affected by mining while the remainder of the increases could be from natural variation, mining or a combination of both.

The pH values for all of the Trapper wells are within the range of natural values for these aquifers. The pH values for the four backfill wells are within the range observed in the other aquifers.

High SAR values are naturally common in the Trapper ground water. Mining does not seem to have affected the SAR values at this site. Sodium values at well GF-7 have varied significantly but, overall, have been fairly steady over the last few years.

The minor constituent variations have been erratic. No changes in these constituents are thought to be attributed to mining. The 2017 through 2020 radium 226 concentrations have been

small which shows that the higher value from well GF-6 in 2016 was a laboratory outlier. The variations in radium 226 concentrations are not thought to be due to the mining.

6.2 SURFACE WATER

Peak flows for the surface water sites at Trapper Mine in 2020 were smaller than peak flows in 2019. The precipitation in 2020 was 13.47 inches, or below the 43-year average for the Trapper Project of 16.4 inches. The previous seven years of annual precipitation to 2005 had been below normal precipitation prior to the larger precipitation in 2005 through 2011, then the very low precipitation in 2012, the near normal in 2013, the slightly above normal precipitation in 2014 and 2015, slightly below normal in 2016, above normal in 2017 and 2019 and below normal in 2018 and 2020. No failures or monitoring site problems were encountered during 2020 and no compliance limits were exceeded in 2020.

Values of total suspended solids (TSS) were generally on the low side of ranges observed in previous years. Total dissolved solids (TDS) were generally in an indirect relationship with flow rate when adequate flow occurred at a site to determine the relationship. The TDS of the surface water from the mine area is similar to the TDS from the non-mined area and, therefore, an increase has not been defined, except for an increase in TDS during low flow conditions at NPDES sites 001 and 011. The TDS, conductivity and major constituents varied over expected ranges with an increase in values as ground-water flow to the stream becomes a larger portion of the total flow. The SAR values measured in 2020 were within the natural ranges for this site. Other chemical constituents analyzed from samples collected from the surface water sites showed little change. The variations and magnitude in iron concentration observed in 2020 were within the range of natural values for these sites. The total aluminum concentrations observed in 2020 were also within the

range in concentrations observed in previous years. The remainder of the minor constituents measured in 2020 were low and within natural ranges. Monitoring data indicates that Trapper Mine sediment control structures prevented any significant impacts on the surface water systems downgradient of the mine in 2020.
