Судебная психология

A 64-year-old female with a 10-year history of rheumatoid arthritis (RA) presented with a 2-week history of progressive weakness and numbness in both lower extremities. She reported difficulty walking and climbing stairs. There was no history of trauma, falls, or recent changes in medication. Her medical history was significant for RA, treated with chronic low-dose prednisone (5 mg daily) and intermittent courses of higher-dose steroids. She had no other chronic medical conditions and was on no other medications. Physical examination revealed mild weight loss and no significant findings on cardiovascular, respiratory, or abdominal examination. Neurological examination showed symmetric weakness in the lower extremities, more pronounced in the legs than the arms, and symmetric sensory deficits in the lower extremities. Reflexes were normal. Laboratory studies, including complete blood count, comprehensive metabolic panel, and thyroid function tests, were within normal limits. Magnetic resonance imaging (MRI) of the spine showed no significant abnormalities. Electromyography (EMG) and nerve conduction studies (NCS) showed a symmetric axonal polyneuropathy. The patient was diagnosed with a steroid-induced peripheral neuropathy. Treatment with intravenous immunoglobulin (IVIG) was initiated, resulting in significant improvement in her symptoms over the next 4 weeks.
