GROUNDWATER LEVELS IN THE DENVER BASIN BEDROCK AQUIFERS 2015

This report updates basic data concerning the depth to and elevation of groundwater in the four main Denver Basin bedrock aquifers collected during the spring and summer of 2015. The report is organized first by aquifer, then by well name. Well completion information is provided, where available. Wells that may be completed in more than one aquifer are listed according to the uppermost aquifer.

Approximately 106 water-level measurements in this year's report were obtained by Division of Water Resources (Division) personnel. A total of seven wells have been instrumented with data loggers to collect daily water-level data. These include the following:

- four wells in the Castle Rock area that monitor all four Denver Basin aquifers; CO3_LTDW (DB-204), CO3_TKD (DB-205), CO6_KA (DB-206) and CO3_KLF (DB-203);
- a well near Bennett, DSSBR01 (DB-020), is completed in the upper Arapahoe; and
- two wells near Golden in the Pleasant View Metropolitan District are completed in the Arapahoe (DB-201) and Laramie-Fox Hills (DB-200) aquifers.

Water-level data from 119 cooperator wells are also included in this report. Personnel from cooperating water districts and municipalities graciously provided these data upon request. The Division appreciates the cooperation of the many entities that provide water-level information.

Tabular data are presented for each well for the previous ten years. Graphical data show the entire period of record for each well. Wells lacking measurements in the past 10 years have been removed from the monitoring program and are no longer included in this publication, although the data are retained in the Division's HydroBase database.

Analyses of water-level changes in the aquifers are based on single point comparisons and may be complicated by unknown pumping schedules or other site-specific hydrologic factors. Table 1 summarizes some of these water-level changes for each aquifer.

Color-coded maps show the change in water levels (by aquifer) for a one (2014-2015), five (2010-2015) and ten (2005-2015) year period. The changes, both positive and negative, are displayed by color in accordance with the map key.

Included in this report is a summary of the Denver Basin hydrogeology with generalized aquifer maps and geologic cross-sections.

Copies of this report can be purchased from the Office of the State Engineer, Records Section, 1313 Sherman St., Room 821, Denver, CO 80203, (303) 866-3581.

An electronic copy of this report, in Adobe PDF format, is available on the Division of Water Resources website

<http://water.state.co.us/groundwater/Levels/Pages/HydroGeo.aspx>.

Additionally, all groundwater level data may be accessed and exported using the tools available on the Colorado Decision Support System:

<http://cdss.state.co.us/onlineTools/Pages/GroundWaterWaterLevels.aspx>

and the Colorado Information Marketplace HydroBase Bulk Data Exporter:

<https://data.colorado.gov/Information-Sharing/DWR-Well-Water-Level/hfwh-wsgi>

or the Colorado Decision Support System MapViewer

<http://water.state.co.us/DataMaps/GISandMaps/MapViewer/Pages/FAQ.aspx>

If you have any questions regarding Denver Basin groundwater and the information in this report, please contact the Groundwater Information Desk at (303) 866-3587.

GEOLOGY OF THE DENVER BASIN AQUIFERS

The Denver Basin is the southern portion of a much larger Denver-Julesburg Basin that extends northward into southern Wyoming and eastward into adjoining states (Fig.1). For groundwater resources administration, the Denver Basin is defined as the outcrop or subcrop of the base of the Laramie-Fox Hills aquifer, which encompasses an area of approximately 6,700 square miles. The administrative Denver Basin extends northward into Weld County near Greeley, into the eastern portions of Adams, Arapahoe, and Elbert counties near Limon, southward into El Paso County near Colorado Springs, and is bounded on the west by the Front Range mountains of Jefferson and Douglas counties. Figure 1 displays the geometry and extent of the four main aquifers that comprise the Denver Basin aquifer system.

The Denver Basin aquifers are composed of sedimentary rock layers, up to 3,000 feet thick in the deepest part of the basin. Generalized cross-sections showing the overlapping geologic formations are shown in Figure 2. In descending order, the hydrogeologic units are identified as the Dawson, Denver, Arapahoe, and Laramie-Fox Hills aquifers.

Extensive studies of these aquifers have been conducted for over 100 years. Water from the aquifers has been used in the Denver area for commercial and domestic supplies since the 1880's. The administration of the Denver Basin aquifers is based on a detailed study completed by the Colorado Division of Water Resources in 1985 as part of a legislatively mandated study commonly known as Senate Bill 5. During the study, the staff of the Division collected extensive information on the nature of the aquifers, the occurrence of groundwater in the aquifers, and the effects of groundwater pumping on surface streams throughout the basin. The estimated amount of water contained in the aquifers is presented in Table 1. Implementation of the South Platte Decision Support System (SPDSS) by the Colorado Water Conservation Board also focused on updating the aquifer geometry, aquifer property, and water level datasets of the Denver Basin. In 2011 the Colorado Geological Survey in conjunction with the Denver Museum of Nature & Science produced two publications refining our understanding of the geology of the water producing formations in the Denver Basin. Also in 2011, the US Geological Survey published the results of a new numerical groundwater model of the aquifer system.

A brief discussion of each hydrogeologic unit within the Denver Basin aquifer system is presented below. For the purposes of groundwater administration, the Division's Senate Bill 5 study is recognized as the authoritative study of the Denver Basin aquifers.

DAWSON AQUIFER

The Dawson aquifer is the uppermost aquifer in the Denver Basin and covers an area of approximately 1,400 square miles. The aquifer varies in thickness, depending on location, and attains a maximum thickness of almost 1,200 feet in the vicinity of Monument. The Dawson aquifer is at or near the land surface throughout its entire areal extent. The aquifer is composed of predominately conglomeratic, coarse-grained arkosic sandstones with minor amounts of interbedded clay and clay shale.

Typical well yields in the Dawson are up to 300 gallons per minute. The northern portion of the aquifer has been subdivided into two hydrogeologic units for administrative purposes. These units are known as the Upper and Lower Dawson aquifers. This separation is based on the presence of an approximately 50-foot thick shale layer that hydraulically isolates the Upper and Lower Dawson aquifer units. The Dawson aquifer is separated from the underlying Denver aquifer by a clay shale sequence ranging from 25 to 50 feet thick.

DENVER AQUIFER

The Denver aquifer covers an area of approximately 3,500 square miles and varies in thickness from a thin eroded edge at its outcrop/subcrop up to 1,000 feet. The Denver aquifer consists of a series of interbedded clay shale, clay, claystone, siltstone and sandstone lenses. The sandstone and pebble compositions are typically volcanic. Carbonaceous material and coal beds are also common.

Due to its finer grained composition, wells commonly have yields of 50-150 gallons per minute. The aquifer is typically developed for domestic uses, though a number of municipal wells have been drilled on the western side of the basin where yields are higher. The Denver aquifer is separated from the underlying Arapahoe aquifer by an extensive clay/shale unit approximately 50 feet thick. The clay/shale interval serves as a hydraulic barrier between the aquifers.

ARAPAHOE AQUIFER

The Arapahoe aquifer is composed of interbedded conglomerates, sandstones, siltstones, and clay shales. The aquifer underlies an area of almost 4,700 square miles and is generally about 400 feet thick. For administrative purposes, the northern portion of the hydrogeologic unit is subdivided into an upper and lower aquifer that is separated by a shale sequence ranging from 50 to 100 feet thick.

The Arapahoe is the most prolific of the four Denver Basin aquifers with wells yielding up to 800 gallons per minute. Consequently, the aquifer is used extensively to supply municipal water systems. Water quality is generally good in the aquifer as evidenced by its use by Deep Rock Water to obtain water for bottling.

LARAMIE FORMATION

The thick shale sequences of the Laramie Formation forms the aquitard or hydraulic barrier that separates the Arapahoe aquifer from the underlying Laramie-Fox Hills aquifer. The formation consists of approximately 400 feet of clay shales with minor interbeds of sandstone and siltstone. Coal beds are common within the formation and have been mined commercially along the eastern margin of the basin. Minor amounts of water are present within the upper sandstones, but are rarely developed for water supplies. Water in the sandstone units is of generally poor quality due to the presence of sulfides and biogenic gas.

The basal portion of the Laramie Formation contains two relatively thick sandstone units (the A and B sandstones) which are hydraulically isolated from the upper part of the formation. These sandstone units, combined with the underlying Fox Hills Sandstone, compose the hydrogeologic unit of the Laramie-Fox Hills aquifer.

LARAMIE-FOX HILLS AQUIFER

The lowermost of the four Denver Basin aquifers is the Laramie-Fox Hills aquifer which underlies approximately 6,700 square miles and marks the areal extent of the basin for economic groundwater development. The aquifer is made up of both the marine sandstones of the Fox Hills and the overlying fluvial sandstones in the lower Laramie Formation. The Laramie-Fox Hills aquifer is generally between 250 and 300 feet thick, and includes about 150 to 200 feet of fine-grained and medium-grained sandstone.

Wells yields of 350 gallons per minute are common. The aquifer is extensively utilized throughout the basin for commercial development and less so for domestic due to the deeper well depths over most of the basin. Both the Laramie-Fox Hills and Arapahoe aquifers are generally under artesian pressure at the present time.

PIERRE SHALE

The Pierre Shale underlies the Fox Hills Formation and is composed of up to 4,500 feet of marine shale with minor sandstone/siltstone lenses. In general, the intermittent sandstone/siltstone intervals in the upper portion of the formation contain sufficient groundwater for domestic uses or for the watering of livestock. This formation defines the lower boundary for development of groundwater for commercial purposes in the Denver Basin.

Figure 1. Extent of Denver Basin Aquifers, from Colorado Geological Survey Special Publication 53.

Figure 2. General cross-section of Denver Basin Aquifers, from Colorado Geological Survey Special Publication 53.

Table 1: Estimated volume of water in storage in the Denver Basin aquifers

AQUIFER	SPECIFIC YIELD (percent)	VOLUME IN STORAGE (millions of acre-feet)
Upper Dawson	20	22
Lower Dawson	20	10
Denver	17	71
Upper Arapahoe	17	12
Lower Arapahoe	17	78
Laramie-Fox Hills	15	102

TOTAL 295 million acre-feet

Note: Based on analysis of drill core from a location near Kiowa, the stated specific yield values may be as much as 25 to 30 percent above an “average” specific yield value for the Denver Basin aquifers. Therefore, the actual volume of water contained in the aquifers may be less than the volumes estimated.
